Links may be categorized as either static (created as a permanent link) or dynamic (created in response to user action). Normally, information packagers pursue dynamic solutions where linking can occur without full control of the resources. This approach is attractive in theory, but may threaten vendors who are less comfortable about open access. Furthermore, as entities create documents that include links, be it at the citation or source level, they need to consider how the source information is captured and authenticated, processing between links, and hosting services. All entities and related protocols need to be interoperable as well as legally compliant (Van de Sompel and Hochstenbach, 1999). Certainly, links within the same website are permissible, but sometimes links to a different website may require permission from the owner of that site; the law is not clear about that issue.

SOCIAL MEDIA

Social media signals a new level of complexity in copyright: the interactive Internet. It fosters collaborative work, which results in collective intelligence. Determining the author and ways to recompense the use of social media works presents a real challenge legally. Furthermore, these documents are often dynamic in nature so that the content may change moment to moment. What, indeed, is the basis of copyright? At best, it would need to be based on a time-stamped version that acknowledges both the time of the creation as well as the time that someone accessed it to use it.

Some people assume that all document on the Internet are free, which assumption is clearly wrong, as discussed above. In some cases, the document creators function on a creative commons agreement, or publish a statement of use. Wikipedia serves as a good example of a community-built wiki that addresses copyright issues. Wikipedia is a good example. It has what it calls a “copyleft” agreement, which states: “Wikipedia content can be copied, modified, and redistributed so long as the new version grants the same freedoms to others and acknowledges the authors of the Wikipedia article used” (<http://en.wikipedia.org/wiki/Wikipedia:Copyrights>). Most of Wikipedia's articles are co-licensed under the Creative Commons Attribution-Sharealike 3.0 Unported License and the GNU Free Documentation License. Wikipedia states that each image notes its legal usage basis.

Blogs are usually the work of a person or group, and are in a recorded form, so they follow normal copyright laws by default. That argument would then also apply to comments that followers make. Of course, the blogger can provide further guidance, be it a statement about being in public domain or a explicit clause that bars anyone from reproducing any of the material in any format.

Podcasts and videocasts consist of compressed audio and video files that are then broadcast by the creator or an aggregator such as iTunes. Again, these are recorded documents so are assumed to

fall within copyright laws. ‘Casts can be easily downloaded and shared, so it is wise to contact the originator or from a reputable Internet site. Difficulties tend to arise when someone uses copyrighted sources (particularly commercial music and videos) to create a mash-up or other kind of derivative work. It can be as simple as videotaping a toddler dancing to a Bruce Springsteen song, and then uploading it to YouTube. Unless the videotaper got written permission from the publisher (or who else owned the copyright) to use that song, the broadcasting that that video constitutes illegal usage if for no other reason than that the song writer and producer should be paid royalties every time the video with the music is played. If the videotaper wants to avoid legal action, he or she should either get permission or not upload or broadcast the video; instead, that video can be recorded for home use, and friends can come over to see the bouncing baby bopper. The Podcasting legal guide (http://wiki.creativecommons.org/Podcasting_Legal_Guide) by Vogel, Marlick and the Berman Center provides current in-depth information on legal uses of these media.

Social bookmarking sites, such as Delicious and LibraryThing, provide a means to store and describe (“tag”) URLs for later retrieval and use. Similar to a bibliography, a list of lists falls under copyright law. Therefore, the creator of each list has the right to determine who can use it and the conditions of its use. To some degree, that can be controlled through the settings that the originator chooses. Usually, each overarching social bookmarking site has a policy about the use of the site as a whole and the use of individual bookmark collections. Increasingly, social media websites such as StumbleUpon integrate social bookmarking, web searching, and blogging.

RSS means “really simple syndication,” and an RSS feed is a means to gather information from other websites to a central location. Every single website that offers an RSS service has its own copyright policy about legal use. Of course, if the originating news is in the public domain and is copied from an open source or creative commons/

copyleft site, then that information can be used freely. One can even broadcast that information via his or her own RSS feed; however, it is usually safer to keep one’s personal RSS feeder private and avoid copyright problems altogether. In terms of copyright law, “really simple” is not really simple.

File sharing is a central feature of social networking, as evidenced by the high use of Flickr and YouTube in particular. Without explicit permission, only the owner of the files can reproduce with work, create derivative works, distribute copies of the work to the public, display or perform the work publicly (including by digital transmission). Therefore, such files cannot be integrated into a school DVD for sale or placed on an institutional website or played at a public meeting. In short, one should read each file-sharing site’s copyright guidelines before downloading documents (Talab & Butler, 2007). Fortunately, some social networking sites include as a searching filter Creative Commons/public domain so that the user can appropriate the file in good conscience.

Intellectual property issues become even stickier when one joins social network sites (SNS) (Wauters, Lievens & Valcke, 2014). Often one has to register to gain access to the network’s files, which translates into providing personal information as the cost for such membership. These websites usually have terms of use contracts, but users tend not to assess the implications and consequences of sharing their own information, such as selling personal information to SNS advertisers. Users should be aware of these practices, and, at the least, check for privacy setting options. At present, SNSs offer little protection to users, and government regulators do not stringently monitor or enforce intellectual property rights. *Caveat emptor*.

Even more fundamentally, crowdsourcing challenges the current notions of intellectual property and copyright (Almeti, 2015). If an editor solicits content, monitors and reviews each input, explains the terms of contributions clearly from the start, and produces a “fixed” work, then copyright is usually not a problem. When the work is created

on a SNS, with each person able to add and edit each other, with no end date and no recorded agreement, then copyright is likely to default to the site's creator and administrator, but the situation can be messy, especially if some kind of commercial or economic benefit is incurred. A Creative Commons license stated at the start of the enterprise is probably the best solution. Technology that can support micro-royalty payments is improving, but the logistics are still daunting. As mentioned before, clear and legally "tight" contracts stipulated from the beginning, and signed before anyone contributes, remain the best solution for the time being.

ADMINISTRATIVE ISSUES

Because everyone has to comply with copyright law, it behooves everyone to be knowledgeable about it, but it can be difficult to keep current. In the final analysis, administrators are responsible for such compliance. Understanding copyright, particularly as it applies to technology, enables administrators to address the risks of technology as they optimize its benefits. The Consortium for Educational Technology for University Systems (<http://www.cetus.org/intellectual-property/>) suggests ways that administrators can oversee intellectual property.

1. Foster intellectual creation, its dissemination, and its use.
2. Develop, implement and enforce technology policies and procedures that optimally support the mutual rights of the academic community.
3. Facilitate the legal and ethical access, storage, and attribution of intellectual works by the entire academic community in coordination with information providers.
4. Review and revise intellectual property policies and procedures in light of technology and cultural changes that impact the academic community.

Digital Rights Management

E

As digital resources grow in number and percentage in institutions, the function of digital asset management has grown in complexity. How do institutions keep track of all their electronic resources as well as make sure that they are effectively stored and retrieved? Especially in today's networked world, digital asset management has to address interactivity options and social networking features, such as push technology, RRS feeds, comment/messaging options, incorporation of faculty repositories, enterprise mash-ups, and user-customizable folksonomy "shells." While some of these features are low-cost plug-ins, their management and incorporation into the library's digital collection system can involve sophisticated technical support, which is usually *not* inexpensive. Furthermore, such customizations need to be well documented and maintained.

Within that scope, the field of digital rights management (DRM) has become increasingly important. Broadly speaking, DRM deals with the exact rights that each digital content has: who holds those rights and under which circumstances, who has authority to access that content and how that can be insured as well as preventing non-authorized people access (Calhoun, 2005). Complying with intellectual property regulations is very difficult; so digital rights management technologies are being employed to control content use. While automated systems conveniently take care of authentication issues and facilitate fair royalties compensation, they can also jeopardize privacy rights and leak into discriminatory profiling practices. E-resources sometimes are not device-neutral, so rights are sometimes given for just one operating system, which belies the concept of intellectual property. Installation of DRM-protected content can be burdensome, and may malfunction, preventing authorized access. At the other end of the process, when the access key to DRM-protected content is lost or the device becomes obsolete, the content itself becomes unreadable, even if it has been paid for

legally. DRM can also pose problems for users with special needs. Furthermore, these DRM digital tools are not standardized. In short, DRM technology may be unavoidable when purchasing some digital resources, but needs to be carefully used (Houghton-Jan, 2007).

Even without considering DRM technology, digital rights management can be complicated. Libraries are usually the body that deals with commercial digital resources, and increasingly deal with institutional digital documents as part of knowledge management initiatives. Within that scope, subscription databases (including e-book aggregators) constitute the major copyright effort because each vendor has a unique set of license agreements. Farb and Riggio (2004) list basic elements of most contracts: scope, completeness of content, duration, warranties, indemnification, access, confidentiality, sharing, archiving, disability compliance, and usage statistics. Increasingly, libraries are considering “leasing with an option to buy” licenses as a way to insure access through backfile ownership; licensing a database with no copyright to the content beyond the date of the license is not attractive.

Training

Faculty need to become aware of intellectual property issues, and their impact on education. However, with awareness sometimes comes fear and over-caution about integrating technology into their instruction. The wiser choice is to empower faculty to safely and successfully navigate copyright law waters. Trainers can share examples of copyright compliance, and have faculty discuss copyright case studies and scenarios such as downloading streaming video or examining licensing fees (Russell, 2010). Other helps include permission forms and checklists of good practices, such as: citing sources thoroughly, linking to sources rather than posting the full text, asking permission to copy sources, checking database terms of use, and using Creative Commons and public domain sources (Disclafani & Hall, 2012; Shin, 2015).

To help the educational community remain in compliance, librarians sometimes provide training about copyright because of their role as information managers. Institutions should also maintain a reviewed bibliography of copyright resources that can be consulted easily. Some good websites that explain copyright follow.

- **U.S. Copyright Office (<http://www.copyright.gov>):** Provides copyright forms and regulations, and a searchable database of copyright registrations.
- **American Library Association Copyright (<http://www.ala.org/advocacy/copyright>):** Good information and links about legislation, intellectual property, and international copyright activities.
- **Columbia University Libraries Information Services Copyright Advisory Office (<http://copyright.columbia.edu>):** Well-respected site targeted to librarians and educators.
- **Consortium for Educational Technology for University Systems (<http://www.cetus.org/>):** University coalition of resources on intellectual property
- **University of Texas (<http://www.utsystem.edu/offices/general-counsel/intellectual-property>):** Many links on copyright issues; they have a good crash course tutorial at <http://www.lib.utsystem.edu/copyright/>.
- **Stanford University Libraries Copyright & Fair Use (<http://fairuse.stanford.edu>):** Focuses on fair use, the public domain, and the permissions process.
- **Copyright for Educators (<http://www.koce.org/classroom/copyright.htm>):** Public television site designed to help educators learn about fair use.
- **Intellectual Property Legal Center (<http://www.cetus.org/fairindex.html>):** Provides information on several aspects of intellectual property, with a separate section on ebooks.

- **Cybercrime (<http://www.cybercrime.gov>):** Computer crime and intellectual property section of the Criminal Division of the U. S. Department of Justice.
- **Software & Information Industry Association (<http://www.siiia.net/Divisions/IP-Protection-Services>):** Their Intellectual Property Division campaign tries to balance enforcement with education.

FUTURE TRENDS

Copyright law tends to react to new technologies and practices, so it is unlikely that it will pro-actively change. Nevertheless, technology will continue to change and expand, so the law will need to respond to, and accommodate, such changes. In addition, technology has also impacted the interchange of information, from the local to the international level, which will affect copyright law directly and indirectly.

Both technology as a whole and the phenomenon of resource sharing is already impacting the publishing model as it develops new models of production and diffusion. Not only do commercial publishers need to address digital formats and ereaders with uneven standards and proprietary operating systems, but they have to deal with unique collations of content, non-commercial competitors, all of which impact the various copyright options. Particularly as product buyers and licensees share these documents, such as libraries and organizations, determining what is a just royalty can be problematic. Micro-payments for access and downloading or printing are being incorporated, but the models for fair rights still need to be hammered out.

Interactive technology corners the market in terms of complex copyright issues. As noted

above, determining the recordable version of a document when multiple users can edit it almost simultaneously can be a copyright nightmare. As mentioned above, documents and repositories are increasingly the products of collective intelligence. In the face of such dynamics, it seems almost laughable to consider that current copyright law allows for proprietary rights for 70 years after the author's death in some cases.

The core concept of a work also needs further scrutiny as works are manifested in so many different formats and appearances. Right now, an e-book might be licensed to be readable on a single device; is that fair if the content itself exists separately from that device? How different does the document have to be in order to be considered a separate work? As the content, container, and metadata elements are considered separately, will copyright elements follow? Especially as web 3.0 emphasizes the relations among documents, those relationship themselves might fall under copyright just as bibliographies and links can.

As this practice expands in global environments, copyright law may need to become more regulated on the international scale so that authors can be fairly compensated. Theoretically, virtual worlds are associated with the country in which the software is based, but such boundaries may also come into question as documents are created in those virtual realities by people in other countries.

This issue of global access also brings up the issue of universal access – for individuals with special needs as well as those with language and linguistic differences. For example, in 2013 the WIPO Marrakesh Treaty required countries to provide technological protection measures to control access to, and use of, digital copyrighted works by people who are print disabled. To what extent is a simpler version or a translation of a document considered a derivative work, especially if it is the result of an automated application? To what extent is automatic captioning covered by copyright? To what extent can fair use be applied?

Particularly as digital programs automate such variations, copyright law will need to be revisited once again.

CONCLUSION

How does the spirit of the U.S. Constitution “to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries (Article 1, Section 1, Clause 8) manifest itself in the 21st century? The countries forefathers could not have imagined the Internet and the semantic web.

Nevertheless, educators and other researchers have the strength of fair use behind them so they can promote an effective learning environment, be it face-to-face or virtual. In addition, collaborative practices such as the Creative Commons promote intellectual sharing in order to advance their fields.

Technology has significantly expanded the intellectual arena in terms of production and sharing of information. In response, copyright law has tried to codify intellectual property rights to balance the rights of the creator and appropriate access to information. Such laws are often format-specific, reflecting both the nature of the medium as well as the perspectives of their producers; however, the content and format are splitting apart so that each digital element may be considered separately. Dissemination models have also changed drastically, so how the information buyer uses that information constitutes another can of copyright worms. The international dimension that technology facilitates adds another layer of copyright issues. Furthermore the dynamic nature of socially constructed information insures that copyright law will always lag behind technology and social behavior. Underlying principles must be the mainstay since practices will continue to vary according to changing contexts.

At the least, leaders and other educators need to keep abreast of copyright issues, and try to comply with them within the context of their use.

KEY TERMS AND DEFINITIONS

Copyright: Laws that regular the use of the work of a creator.

Crowdsourcing: Practice of enlisting the help of many people in order to generate content, particularly in online environments.

Creative Commons: A nonprofit organization that seeks to make creative work available for others to build on while respecting intellectual property rights.

Digital Rights Management: Access control technologies used to protect the copyright of electronic media.

Fair Use: The legal conditions under which one can use copyrighted material without obtaining permission and paying royalties.

Intellectual Property: Any intangible asset that consists of human knowledge and ideas; the ownership of ideas.

License: Permission granted by authority to exercise certain rights and privileges that would otherwise constitute an illegal act.

Open Access: Free availability on the public Internet.

Open Source: Coding that is freely available to the public, usually applied to software development.

Social Media: Interactive web; enables people to collaborate and share online.

Employing Educational Robotics for the Development of Problem-Based Learning Skills

Nikleia Eteokleous

Frederick University Cyprus, Cyprus

INTRODUCTION

The technological improvements within the robotics field and its expansion to various fields such as medicine, industry and education, calls for robotics integration within the educational practice as learning tools. Robotics in the classroom has taken a global momentum especially because of its positive contributions in the teaching of science, technology, engineering and mathematics (STEM) (Benitti, 2012). Additionally, research has shown that robotics integration in education promotes the development of various non-cognitive skills, however extremely important life skills. For example, reasoning, problem solving, tinkering, sequencing, computational thinking, decision making, scientific investigation, collaboration, knowledge construction, critical thinking, creativity, communication (Bers, Ponte, Juelich, Viera & Schenker, 2002; Benitti, 2012; Chambers & Carbonaro, 2003; Eteokleous, 2016; Miglino, Lund, & Cardaci, 1999; Resnick, Berg, & Eisenberg, 2000; Williams, Ma, & Prejean, 2010).

Educational systems are responsible in preparing students (future citizens) for this ever-changing Hi-Tech, globalized, interconnected world. Numerous 21st century skills are reported in the literature as important to be developed by future citizens as the means to address the needs and demands of the society. The 21st century skills have been outlined and described by various researchers and reports (e.g. Ananiadou & Claro, 2009; Bybee & Fuchs, 2006; Griffin & Care, 2005; Mojika, 2010; Rotherham & Willingham, 2010; Trilling & Fadel, 2009), and can be summarized

DOI: 10.4018/978-1-5225-2255-3.ch217

as follows: communication, collaboration, critical thinking, problem solving, knowledge construction, creativity – innovation, self-directed learning, global citizenship and digital literacy. The changes in the global competition and collaboration, the focus on service economy, as well as the information growth, constitute the development of the 21st century skills extremely important. Given the aforementioned, the workforce needs have changed, the job tasks and type of work are changing and consequently the required skills are changing.

Problem solving and digital literacy is one of them and robotics and programming are becoming important elements within the educational settings. The students need to be provided with the opportunities to experience tinkering, fabrication, design and create technological artifact & interactive objects, construct their own meaningful projects, experience the scientific method of inquiry (Bers, 2008a; Bers, 2008b; Bers, Matas & Libman, 2013; Bernstein, Mutch-Jones, Cassidy, Hamner, & Cross, 2016; Eteokleous, 2016). Consequently, educators need to design the appropriate learning environments where students have the opportunity to develop the aforementioned skills.

Main Aim

Robotics activities are related to addressing a problem, and usually problems in authentic, real situations. The students are given a driving question and are requested to solve a “problem”. Having noticed this connection in relation to the pressing need to develop 21st century skills, the

current study evaluates the integration of robotics as an educational tool within the teaching and learning process where the problem based learning (PBL) method and the interdisciplinary approach are intertwined. Specifically, robots are used as cognitive-learning tools in order to apply the problem based learning method in early elementary grades (2nd and 3rd graders) in curricular-integrated activities (interdisciplinarity). More importantly, the study aims to examine whether the integration of robotics as cognitive-learning tools influence the development of the following PBL skills: creativity - innovation, critical thinking, and collaboration.

BACKGROUND

Educational Robotics

The idea of robotics integration in education has been around for more than 20 years (Miglino, Lund, & Cardaci, 1999; Papert, 1980). However, the great revolution in the field of educational robotics has been achieved throughout the last decade, where robotics escaped the laboratory and made efforts to connect to education (Chambers, & Carbonaro, 2003). The robotics materials (building blocks/bricks, sensors and motors) are perceived as toys by the children and research revealed that regardless of age, educational background and interests, students consider working with robots to be “fun” and “interesting”. (Chambers & Carbonaro, 2003; Williams and Prejean, 2010). Numerous research studies suggest that robotics integration for educational purposes is an effective teaching method; arguing that if robotics activities are appropriately designed and implemented have great potential to significantly improve and enhance the teaching and learning process (Benitti, 2012; Bauerle, & Gallagher, 2003; Bers et al., 2002; Eteokleous, Demetriou, & Stylianou, 2013; Papert, 1993).

Research has shown that robotics integration in education promotes the development of student higher-order thinking skills such as application,

synthesis, evaluation, problem solving, decision making, and scientific investigation (Bers et al. 2002; Chambers & Carbonaro, 2003; Resnick, Mojica, 2010; Berg, & Eisenberg, 2000). In order to achieve the above, robotics need to be integrated as tools and not as subject matters in the educational practice. When robotics is integrated as a subject matter, as an autonomous entity, and not within a well-designed lesson plan, there is limited educational potential and value. On the other hand, robotics integration as a learning tool, in selected teaching cases exploits its full potential; therefore it upgrades and enhances the teaching and learning process and promotes school transformation (Eteokleous, et al., 2013). The intention of this approach is not to learn how to use the robotics package, and its programming software, but to use it as a tool within a specific educational context to achieve learning objectives. In other words, robotics is employed as a tool to teach and deliver concepts within various subject matters such as Mathematics (Whitehead, 2010), Engineering (Craig, 2014), Science (Vollstedt, 2005), Physics, and even in non-technology related fields such as Biology, Psychology (Bers, Ponte, Juelich, Viera & Schenker, 2002; Eguchi, 2007, Eteokleous, et al., 2013; Craig, 2014). *Robotics integration* in the teaching and learning practice is defined as the use of robotics by students as a tool that enhances their learning experience and supports the achievement of specific learning goals (Ward, et al., 2012; Eteokleous, et al., 2013).

Problem-Based Learning (PBL) and Robotics

Problem-based learning is an instructional method characterized by the use of “authentic” problem sets, as contexts for students to develop critical thinking and problem solving skills, and acquire the necessary course concepts. Along the same lines, problem based learning is defined as “a systematic teaching method that engages students in learning knowledge and skills through an extended inquiry process structured around complex, au-

thentic questions and carefully designed products and tasks” (Markham, 2003, p. 4). Additionally, PBL is defined as the approach that challenges students to learn through engagement in a real problem or situation (Domin, 1999; Duch, 1995; Grant, 2009). Students are presented with real-world, multidisciplinary problems that demand critical thinking, engagement, and collaboration. Given the aforementioned, it is a challenging and demanding process, requesting students to use various types of thinking in order to realize, capture and solve the problem given.

Usually robotics activities are related to addressing a problem, and sometimes problems in authentic, real situations. The students are given a driving question and are requested to program the robots in order to perform a number of activities, aiming to solve a “problem” and/or achieve a goal (Gibbon, 2007; Varnado, 2005). There are also studies showing improvements in problem solving skills as well as self-regulation, recognition, orientation skills (Baker, Nugent, Grandgenett, & Adamchuk, 2012; Karim, Lemaignan, S., Mondada 2015). Having noticed this connection, the current study aims to bring together the PBL approach and robotics integration in the educational settings, in order to examine the role of robotics in promoting the development of specific problem-based skills (creativity-innovation, critical thinking and collaboration) in early elementary grades.

The learning environment where robotics are employed as educational tools includes exercises and activities where the problem-solving process is integrated. Therefore, the students are actively involved in designing, building and organizing the entire process in order to reach to a solution (to solve the problem). Additionally, in order to solve the problem, the students need to construct the appropriate robotic model as well as program it. Construction and programming provide instant feedback to students, where the students can take corrective actions through experimentation and experience the process of testing and re-testing (Alimisis, 2009; Arlegui, Menegatti, Moro, Pina, 2008).

The Educational Robotics Package

There is a great variety of educational robotics packages (BeeBots, BlueBots, Thymio, Cubelets, Roamer, LegoWeDo, Engino, Lego Mindstorms). For the purposes of this research the BeeBots robotics package was employed. The reasons for choosing the BeeBots were due to their characteristics and ease of use given the fact that the students did not have any other experience with robotics. The BeeBot is a colorful, easy-to-operate, and friendly little robot that invites students to experience sequencing, estimation, problem-solving, and many more. It can be programmed to move forward and backward for 15 centimetres, and to turn 90° right and left. The robot can store up to 43 steps. It has also the Pause button, which is considered as a step. It can be programmed in order to perform various educational exercises using specific floor mats (i.e. alphabet mat, geometry shapes mat, treasure island mat). The floor mats are necessary since the BeeBots are programmed to perform various activities using floor mats of different concepts.

RESEARCH METHODOLOGY

A descriptive case study approach was employed collecting both quantitative and qualitative data (Cohen, Manion, & Morrison, 2008; Yin, 2003). Classroom interventions were designed and implemented for two months in two classes: 2nd and 3rd grade. The population of the study was 43 primary education students: 21 2nd graders and 22 3rd graders. Two elementary school teachers and two teacher assistants closely collaborated with the Robotics Academy in designing and delivering the lessons. Specifically, The Robotics Academy at Frederick University (Department of Education) (<http://akrob.frederick.ac.cy>, <https://www.facebook.com/AkadimiaRompotikis>), is a research and educational unit that aims to promote and conduct research in the area of robotics education. The Robotics Academy had the overall responsibility

Table 1. The floor mats developed by students

Grade	Subject Matters	Floor Mats
2 nd	Mathematics	Solid shapes
	Language and Linguistics	Our school map
	Arts	<i>Developed the floor mats</i>
3 rd	Language and Linguistics	The Alphabet
		Word Search Puzzle
		Professions of the Past
	Arts	<i>Developed the floor mats</i>

to professionally train and educationally and scientifically support the teachers and the assistants, and provide the educational robotics packages. They attended one-week intensive professional development training on educational robotics. The teachers were given the flexibility to choose the disciplines (topics) that they thought it would better fit to robotics.

The classroom intervention duration was 5 weeks, involved various disciplines (interdisciplinarity) and was divided in three phases. During the 1st phase the students were given an interactive presentation regarding robotics, its usefulness and value in our daily life. At the 2nd phase, during the Arts Course, the students collaborated to design and develop the floor mats to be used as educational material within other disciplines. Specifically, the 2nd graders developed two floor mats: The Solid Shapes and The School to be used in Mathematics and Health Education respectively. The 3rd graders developed four different floor mats: The Word Search Puzzle, Professions of the Future, The Similes and The Alphabet to be used in the Language and Linguistic Course and Geography (See Table 1). Finally, during the 3rd phase the teachers delivered the lessons designed where robotics employed as cognitive learning tools through various exercises.

Questionnaires and focus groups with the students, as well as classroom observations conducted by the researcher's team were the main methods of data collection. Three different instruments were used, where each instrument measures different

problem based learning skill: 1) innovation - creativity, 2) collaboration, and 3) critical thinking. The instruments were taken from the Buck Institute of Education (www.bie.org) and were adjusted for the purposes of this study. They were translated in Greek and pilot tested. Specifically, two teachers and five students participated in the pilot study. The authors took into consideration the teachers' and students' comments and accordingly adjusted the instruments.

The instruments were used in order to develop the three data collection methods: questionnaires, observations and focus groups. Pre- and post-questionnaires were given to students. The questionnaires were different for each grade due to the age of the students (as suggested by the Buck Institute of Education). For the 2nd graders a simple form of questionnaire was given, where a combination of smiley / sad faces and phrases (as responses) were used. However, for the 3rd graders a different form of questionnaire was used; they were required to address various statements using a 5 likert-type scale. (See see Table 2).

The observation templates and the focus groups protocols were developed based on the same parameters as the questionnaires in order to record and evaluate the development of the PBL skills as well as to overall examine the teaching intervention. Observations were conducted throughout all lessons delivered. Additionally, four focus groups were conducted (two focus groups for each grade) by the completion of the classroom interventions. A total of 15 students participated

Table 2. The PBL skills questionnaires

Grade	Questionnaires	Parameters	Questions	Question Type
2 nd	Critical Thinking		6	3 point - Likert scale
	Collaboration		5	
	Innovation – Creativity		6	
3 rd	Critical Thinking (4)	Analyzing driving question and begin inquiry	2	5 point - Likert scale
		Gather and evaluate information	2	
		Use evidence and criteria	3	
		Justify choices	2	
	Collaboration (6)	Takes responsibility	4	
		Helps the team	4	
		Respects others	2	
		Makes and follows arrangements	4	
		Organizes work	2	
		Works as a whole team		
	Innovation – Creativity (4)	Define the creative challenge	1	
		Identify resources of information	1	
		Generate and select ideas	4	
		Present work to others	1	

at the focus groups: seven 2nd grade students and eight 3rd grade students. The students were selected on a voluntarily basis. Through the focus groups the researcher's team was also aiming to capture students' reactions, experiences and opinions regarding the teaching intervention.

The quantitative data collected from the questionnaires were used to perform descriptive (frequencies, percentages, cross tabulations) and inferential statistics (t-test, ANOVA). The SPSS package (version 19) was used. The qualitative data collected through observations and focus groups were analyzed by using the continuous comparison of data approach (Maykut & Morehouse, 1994).

MAIN FOCUS OF THE PAPER

Through the activities designed, the students were involved in the extremely interesting process of programming and controlling the robots. The activities performed with the robots besides being enjoyable and creative; they promoted learning

by playing, and specifically the development of some of PBL skills. Specifically, the analysis of the pre- and post-questionnaires revealed the development of the creativity-innovation and the critical thinking skills. However, the collaboration skills were not developed as much as the aforementioned skills. This is due to minor conflicts observed within the teams while trying to design and develop the floor mats as well as to program the BeeBots. Students were so excited in using the robots that the majority of them were very anxious in holding, touching and programming them. In some cases it was impossible for students to hold turns in using the BeeBots. Finally, no statistical significant differences were revealed in regards to age and gender.

The observations and the focus groups complemented and further explained the results of the questionnaires in regards to the development of PBL skills. Additionally, several issues were revealed in regards to teachers' and students' role, difficulties encountered, student attitudes and opinions.

The observations assisted also in gaining and evaluating information on issues that cannot easily and/or directly addressed through the questionnaires. The observations showed that during the lessons where the robots used; more time was needed than the allocated time for each teaching period (40 minutes). The aforementioned was observed in almost all courses (i.e. Maths, Health Education, Language and Linguistics) besides the Arts. Also, observations revealed that although students followed the directions given by the teachers and addressed the exercises and problems given, they wanted to be granted time to “play” with the BeeBot. One of them mentioned “...we want to develop the different paths for the BeeBot...”. The robots intrigued their imagination and creativity in developing by themselves the routes for the BeeBot to follow. They also reported that they wanted to develop activities for other students to solve (program the robots).

The role of teachers was extremely important in helping the students, guiding, monitoring and facilitating the teaching and learning process. Additionally, the presence of a teacher assistant deemed necessary in order to provide any assistance needed to the teacher, since in some cases the students were anxious and excited, given the hands-on character of the activities and the student-centered learning environment developed.

Finally, the focus groups helped the researcher looked for themes that helped her in gaining better understanding and more information on students’ experiences and opinions. The majority of the students reported that the educational robotics experience was extremely enjoyable and very interesting. Overall, the students examine various concepts (interdisciplinary approach) by programming the BeeBot, having the chance to develop various knowledge and skills through the process of programming. The students experience the multifaceted process of problem solving and decision-making, as well as cultivate collaborative and exploration skills.

FUTURE RESEARCH DIRECTIONS

E

The results of the study provide the foundation to further investigate robotics integration in the teaching and learning process. Some more studies were designed and implemented in relation to the aforementioned end, where different educational robotics packages (Lego WeDo, Lego EV3, mBots) are used for the development of problem-solving based skills. Additionally, BeeBots and Lego WeDo are being employed within a newly designed innovative curriculum developed by Frederick University Robotics Academy (<https://www.facebook.com/AkadimiaRompotikis/>) in order to examine the development of computational thinking, self-regulation and spatial skills in elementary schools students. Last but not least, the impact of robotics in developing self-confidence and self-fulfillment to special needs students is planned to be examined the upcoming semester.

CONCLUSION

Overall, the study reveals the great potential of integrating robotics as a cognitive-learning tool across disciplines in order to achieve problem-based learning skills. It examines the integration of robotics within a formal in-classroom setting in contrast to other studies that examine in-formal and non-formal educational settings. Additionally, it focuses on early elementary grades, whereas other studies focus on 5th and 6th graders and even more on secondary education. The results of the study aim to promote research in the field of educational robotics in order to further examining and defining the appropriate learning pedagogies and teaching approaches to be employed when robotics is integrated as cognitive-learning tool. It also highlights the need for teachers to be professionally trained, supported and guided. Finally, the study suggests the value of adopting appropriate robotics packages, learning pedagogies, and teaching

approaches when robotics and programming are integrated within classroom activities. The focus should be to engage teachers in using robotics and programming in their classrooms across disciplines.

KEY TERMS AND DEFINITIONS

BeeBots: A colorful, easy-to-operate, and friendly little robot that can be used by students from the age of four to the age of ten, depending on the level of programming difficulty of each exercise.

Educational Robotics: The use of robotics in the teaching and learning process (in the educational practice) as a subject matter and/or as a cognitive learning tool.

Floor Mat: A paper or foam based mat (mainly located on the floor or high-table) which is separated in blocks of 15X15 centimeters. Each floor mat represents a specific theme/ concept and each block depicts different sub-theme/ sub-concept related to the overall theme/ concept. Each floor mat may have from 9 to 24 blocks (or even more!) Floor mats can be developed for various subject matters.

Interdisciplinarity: It is the employment of various disciplines. The purpose is to relate/ combine two or more subject matters (or academic disciplines) into one exercise/ activity in achieving specific educational objectives.

Problem Based Learning (PBL): The students are involved in a learning process where they needs to solve a specific problem using various knowledge and skills. This approach can be used within various subject matters even.

Robotics Packages: In the education market there are various robotics packages that allow users/students to construct and program robots. These packages mainly contain bricks, wires, sensors and a visual programming software.

Twenty (21st) Century Skills: The skills that considered to be important and necessary for

student to develop in survive and succeed in the 21st century. Those are: problem solving, critical thinking, collaboration, communication, global citizenship, digital literacy, knowledge construction, creativity, innovation, self-directed learning.

From Digital Exclusion to Digital Inclusion for Adult Online Learners

E

Virginia E. Garland

University of New Hampshire, USA

INTRODUCTION

In this second decade of the new millennium, it is becoming clear that nations are pressuring their citizenry to become more technologically skilled in order for them to compete globally in the quest for political, economic, military and scientific success. Educational leaders are also aware of the need to provide more “tech savvy” students who can be successful academically, socially, and professionally in the international arena (Garland & Tadeja, 2013). Adult learners are taking a greater role in that process of becoming better academic and digital citizens. For instance, “Goal 2020” of the United States Department of Education is a higher education reform policy initiative focused on the United States leading “the world in the proportion of college graduates” with “at least 8 million additional adults [who] will need to return to college and earn associate and bachelor’s degrees by the year 2020” (Gast, 2013, p.17). But the goal of digital literacy for all the world’s people is hampered by many factors.

There are wide disparities in Information Science and Communication Technologies (ICT) skills between digitally excluded and digitally included online learners both nationally and internationally. There is an enormous and even widening gap between Internet users in developed versus developing nations (Pick & Azari, 2008). There are also digital exclusion issues in the United States and in other economically advanced countries. Secondary level students in the United States are increasingly taking online courses; but those public school students who live in low socio-economic areas, who speak a language other

than English, who are considered minorities, and who are disabled are more likely to lack academic technology skills (Garland, 2015).

In addition, a significant number of adult learners across the globe are a new group of “digitally excluded” students. Distance education courses are increasingly being taken for academic, professional, and personal reasons by students who are over twenty-five, yet many are struggling to compete with their “digital native” peers. According to one study, “Expanding adult digital literacy is essential for confronting vulnerable adults’ issues of exclusion and marginalization that are increasingly being amplified by the digital mediation of modern social life.” (Jacobs et al, 2014, p 626) Adult learners also need full inclusion in the technological demands of online education.

This chapter focuses on current trends in digital exclusion of adult learners and provides some solution strategies for ICT directors, higher education administrators, online instructors, and the older students they serve.

BACKGROUND

The most recently available statistical data indicate that online degree programs have a significant impact on adult learners. Over one fourth of all higher education students are taking online courses. According to the National Center for Educational Statistics (NCES) report, “Distance Education,” 25.8% of all undergraduate and graduate students were “enrolled exclusively” (12.5%) or “enrolled in some” (13.3%) distance education courses in 2012 (NCES, Distance Education,

para 3). NCES indicated in its “Back to school statistics” report that “In 2013 there were about 12.2 million college students under age 25 and 8.2 million students 25 years old and older” (NCES, Back to school statistics, para 16). By the year 2024, these enrollments are projected to almost double, with over 23 million “total fall enrollment in degree-granting postsecondary institutions,” the majority of which, over 13 million, are expected to be women (NCES, Digest of Education Statistics, table 303.40). In addition, the number of adult students taking non-degree online programs is also increasing. McCallum (2012) states that there are over 90 million students over 25 years old who are taking post-secondary studies in the United States alone. To put a human face on these statistics, consider the case of an online adult learner named Rosa.

In the fall of 2015, the author was introduced to Rosa (identifying information removed) in Texas at a national leadership conference, which focused on the accomplishments of undergraduate and graduate students. Rosa, whose primary language is Spanish, is the first in her family to go to college. Despite her academic success in being awarded a partial scholarship for her undergraduate studies, Rosa confided in me that she was struggling with financial and time management issues in trying to complete the online courses of her program. Rosa is a recently divorced, single mother of two young children. She spends most of her time working and taking care of her family. Rosa and her children have had to move back in with her parents. She does not have the resources to afford a smart phone and the latest computer upgrades. Although she is working part-time and saving money to make the tuition payments of her current degree program, Rosa feels that she might have to discontinue her undergraduate studies. It is likely that this academically talented adult student will drop out of college.

Digital exclusion of adult learners is associated with technology, socio-economic and gender factors. Sadly, Rosa fits the profile of many digitally excluded online adult learners. She is a mature

student, over the age of twenty-five, who does not have the requisite technology skills and tools to be able to easily access the Internet and to effectively use the information and communication digital tools prevalent in online courses. Rosa is also a non-traditional student, a single mother who was drawn to the flexibility in her schedule promised by the lure of distance education programs.

Why do adult students like Rosa want to take online courses? They find that online courses are appealing because of their “anytime, anywhere” access. Britt states “students desire more control over their education along with a flexible schedule in the learning process which is a distinct advantage of online education” (2015, p. 400). But some mature students are “digitally excluded,” unfamiliar with and perhaps unable to afford the newer technologies that are used as instructional tools in online courses (Garland, 2009).

Non-traditional students need not only technology training but also access to current digital tools in order to be successful online learners and more effective professionals. According to Gast (2013), the reasons for adult learners’ desire to take online programs include “the need for updated skills to compete in a knowledge based economy, a change in demographics due to immigration and higher retirement ages, technological advances bringing the classroom to the student, and a globalization of the higher education system. Most recently, online and for-profit institutions have been a primary beneficiary of this growing enrollment trend among adult learners” (p. 18). Indeed, online degree programs have almost doubled in a recent ten year period, “62.4% of colleges offered online degree programs at the end of 2012 which is up significantly from 32.5% in 2002” (Britt, 2015, p. 399).

Although the number of online degree programs at more traditional colleges in the United States is increasing, some previously programs in distance education universities are in decline. Two distance education giants, the University of Phoenix and Corinthian Colleges, have sharply decreasing enrollments and increasing public scru-

tiny. At the University of Phoenix, the largest for-profit university in the United States, “enrollment numbers have been cut in half from five years ago, down from 460,000 to 213,000...[and] Corinthian Colleges, another major for-profit system, closed its doors amid legal action and accusations of financial manipulation towards students” (Jackson, 2015, para 5 & 6). One reason for enrollment declines at the University of Phoenix is competition from other distance education programs, but another reason is the attrition of adult learners in online courses.

SOCIO-ECONOMIC, GENDER, AND TECHNOLOGICAL ISSUES

Despite the exponential growth of both distance education courses and the number of adult learners who are taking them, the dropout rate of students over twenty-five years of age is high (Park and Choi, 2009). Key factors that inhibit the academic success many adult learners in online courses are socio-economic, gender and technology based. These issues are helpful in understanding why certain groups of adults are especially underserved in their need for digital inclusion. They include the poor, mostly women, who have minimal literacy skills and speak English as a second language. The Literacy, Language, and Technology Research Group (LLTR) from Portland State University recently studied (Jacobs et al., 2014) the need for “adult digital literacy learning” in a technologically advanced “multiliterate world.” These researchers found that the “digital newcomer” is “economically vulnerable, under-served, and high-need adult population (i.e., low-income, low-literate, elderly, and English Speakers of Other Languages) who are new to, or have limited experience with, technology” (p. 625).

Constraints on the Adult Learner

If working adult learners, many of whom are single mothers like Rosa, had more time to take

affordable online courses, they would be less likely to drop out. Based at one of the world’s largest online universities, University of Phoenix, faculty members Donnelly and Kovacich (2014), studied adult student attrition in community college based online courses in the Boston, Massachusetts area. The adult students of their study have the same characteristics of those researched by the LLTR group in Portland, Oregon. Donnelly and Kovacich found that poor, working women with children are likely to fail or drop out, stating that “Over 80% of community college students work as well as attend school, are raising children, and care for relatives... attrition rates for online courses at community colleges are 15% to 50% higher than the same courses provided in face-to-face environments” (p. 35). In a study of adult learners in Hellenic Open University, Greece’s “only university offering exclusively distance education courses,” Angelaki and Mavroidas (2013) found that women were more likely to experience “negative emotions... mainly associated to the unknown for students [sic] methodology of distance learning, the requirements of the course, the familial, professional and social responsibilities of the students as well as to the difficulties stemming from using technological tools” (p. 88).

Online adult learners who determine that their online courses are a “waste of time and money” are more likely to drop out. Gast (2013) contends that fiscal and time management factors are key in understanding why adult learners fail to complete online courses. The latter researcher studied economically disadvantaged, mature students, and found that “Time and finances are cited as the most common barriers faced by adult students.” (p. 18). Even if adult students can afford their online programs, they might not have the time needed to complete the required assignments. Romero and Barbera (2011) found that there are time constraints for the older learner who has more work and family responsibilities than his or her younger peer. Similarly, Herbold (2012) states that “time” is valued more by the “non-traditional, older students...With restrictions on

their time due to life's other responsibilities, adult learners are better able to successfully complete a course of study if the conditions for learning are optimized" (pp. 117-118). Solutions for delivering effective online instructional strategies that make the best use of the adult learner's limited time and financial resources are provided in the "Solutions and Recommendations" section of this chapter.

Technology Skills and the Adult Learner

With access to effective, wireless technology tools that deliver a curriculum that is relevant, the adult student has a greater chance of success in online courses (Garland 2015). In her study of 69 graduate students in two online education courses, Herbold (2012) also found that "Students could access the course from any location they had Internet access, which could be anywhere with a portable smart device. The place could also be a fixed location such as a desk computer or laptop at home, work, or public places with Wi-Fi like the library, coffee shop, hotel or truck stop. These mature students can access the classroom from almost anywhere their busy and involved lives take them" (p.122).

However, even if adult online learners have Internet access tools, such as the "portable smart device" described by Herbold (2012), they might still be inexperienced in "digital literacy" skills. Many people born before the "iGeneration" have smart phones, but they are more likely to use them for communication and social media purposes than as tools in the academic assignments of online courses (Garland, 2009). According to Jacobs et al (2014), "engagement with Web 2.0 involves a new ethos or way of understanding one's relationship to knowledge construction...[The] dichotomy of digital natives and digital immigrants has been found to be overly simplistic and in need of more nuanced understandings of what it means to be able to use the computer and Internet" (p. 625). Thus, a discussion of the term "digital inclusion" must include not only access to the Internet, but also the technology skills needed for the adult learner to be fully engaged in the online course.

SOLUTIONS AND RECOMMENDATIONS

These are the major intervention strategies needed to ensure success for the adult online learner:

- Technology training and support for adult online learners in the use of the digital tools used in distance education programs
- Organizational and time management skill training for adult students to become more self-directed learners
- Curriculum design and teaching methods training for online instructors and academic coordinators
- Increased financial assistance opportunities for those most in need, the at risk, non-traditional student
- Expanded and affordable childcare programs, especially for working mothers who are also online learners

In addition to the policy initiatives at the international and national levels to make online courses more affordable and accessible to adult learners, there should be local efforts to engage the mature student. Institutions of higher education must develop and implement policies that better ensure the success of adult learners, whose enrollment projections, particularly those for women, are greater than those of their younger counterparts.

Attrition is decreased if colleges and universities support the acquisition of academic and technology skills that enable the mature student to be successful. The online course curriculum should also be meaningful to the adult learner. According to Park and Choi (2009), adult learners were less likely to drop out of online courses if they had "organizational support" and that they viewed the course to be relevant to their personal and professional lives. ICT directors and university administrators should be aware that "Adult students have many commitments such as family and work in addition to school and must create the time and energy to manage them all. Schools need to understand how outside factors can hinder

the adult learning process and take steps to fully understand the plight of adult learners” (Donnelly and Kovacich, 2014, p. 40). Adult student advising programs and financial assistance opportunities would benefit the mature learner. But the adult learner must also be engaged in self-directed learning.

Stine (2010) found these three factors as key to the success of adult learners in distance education: high levels of student skills in technology, academics, and individual learning. One model program for preparing adult learners for online courses is the Learner Web project of Portland State University for digitally excluded, “high need” adults, “designed to give learners a self-directed learning experience...the shifts learners undergo as they gain experience and confidence with digital tools can help educators develop more robust systems for supporting vulnerable populations” (Jacobs, et al, 2014). Even non-vulnerable adult learners need to be self-directing in their online coursework. According to Jacobs’ (2012) study of online graduate students, “to address the adult learning characteristics of being autonomous, self-directing and self-responsible, students were given the latitude to select the activities they preferred and that would best meet their individual needs” (p. 122). Thus, self-directed learning is an approach that is valuable in motivating the older online learner.

The adult student who takes more control of his or her own online learning would also benefit from effective time management skills. In their study of community college students who dropped online courses, Donnelly and Kovacich (2014) found that those who had higher attrition rates also had little time to focus on studying because of other tasks, such as work and family obligations. In addition to suggesting that some online adult learners study more effectively in the morning, the University of Phoenix faculty members, Donnelly and Kovacich (2014), along with Romero and Barbera (2011), recommend that more interactive course design features would also enhance student engagement in synchronous online learning activities. Adult

students who were interviewed by Donnelly and Kovacich (2014) in the community college online courses study stated that they did not drop out of online courses if they were effective in organizing their course schedules and assignment deadlines.

Mature students need other motivational tools, such as having achievable goals and knowing that the instructor is meeting their needs for collaboration and evaluative feedback. Adult students are more goals oriented than their younger peers. Ekmekci (2013) found that adult students will find online courses “a waste of time” unless they are taught by knowledgeable instructors with clearly stated goals that are relevant to students’ professional lives. The goals of online courses, such as the completion of multimedia group projects, are more easily attainable with formative assessment strategies.

According to Leong (2011), other instructional strategies to enhance the success of online adult learners include the instructors’ use of both collaborative activities to improve “social presence” and immediate feedback on assignments to increase “cognitive absorption” of the content being taught. Ke (2010) believes that there are three types of “presence” needed in the online course: cognitive, social and instructional. Online dialogues and prompt, effective feedback by the online instructor are viewed by Ke as ways to increase these three types of “presence.” The need for a “social presence” between instructor and student, and often between student and student, cannot be underestimated. In their study of distance education programs for adult learners in Greece, Angelaki and Mavroidis explain that “The expanded use of new tools related to Information and Communication Technologies (ICT) facilitates communication, cooperation and dialogue among participants in distance learning courses” (2013, p. 78). In addition to the value of social presence is the importance of cognitive presence. Leong’s and Ke’s findings are similar to that of Tyler-Smith (2006), who argues that “cognitive overload” is the most significant reason that the adult “eLearners” he studied in New Zealand

dropped out within the first weeks of the online courses they were taking.

The adult learner also needs to be able to afford the tuition of distance education degree programs. Despite enormous national investment in higher education, adult learners in the United States are those with the largest student debt. According to The Hechinger Report (2015), “The reason that the ‘average’ student’s debt is so high – almost \$23,000 – is because the figure includes the loans of graduate students, who are permitted to borrow unlimited amounts from the federal government up to the cost of attendance. Sixty-five percent of 2012 graduates who borrowed \$50,000 or more were graduate students” (para 5). In addition, Gast (2013) found that student loan debt is a significant inhibitor to adult student enrollment.

The single mother who is at risk of dropping out needs not only financial aid but also improved social and family support. In a study for the Institute for Women’s Policy Research, Gault, Reichlin, and Roman (2014) recommend that federal and state student financial aid programs apportion more assistance to low-income adult learners. These researchers also advocate “more inclusive campus policies,” to meet the needs of single mothers, such as increased child care subsidies and support as well as “single-parent housing.”

FUTURE RESEARCH DIRECTIONS

The attrition of adult learners in higher education online courses is an emerging field of research. Longitudinal studies of distance education programs and the mature students they serve are needed. Political science, adult motivational and women’s studies theorists can inform ICT and educational practitioners on the reasons for the alarmingly high dropout rates for adult students in distance education programs in community colleges, which have received an infusion of federal assistance in the past few years.

In the United States, policy makers and politicians are making a wide variety of recommenda-

tions to alleviate the alarming increase of student debt. One policy highly criticized is the 2010 Health Care and Education Reconciliation Act (a section of which is the Patient Protection and Affordable Care Act or “Obama Care”). Although this legislation invested two billion dollars in community colleges and “career training, student attrition and student debt have reached all time highs. Political scientists and educators need to further study the projected effectiveness of financial assistance or student debt relief programs.

Adult motivation theories also shed further light on the ways to ensure the success of non-traditional students in online courses. In a study of 203 university students, Sogunro (2015) found eight factors that motivate adult learners in higher education: effective instructional methods, solid curriculum, course relevance, interactive classroom, formative and prompt assessment, student self-directedness, positive learning environment, and meaningful academic advising. All of these factors can apply to the online course; especially those focused on curriculum design, interactive technology tools and feedback methods. And, adult learners particularly need a curriculum that is relevant and advising that is supportive. More research should be conducted on the application of adult motivational factors to the design and implementation of online courses in order to reduce the high rate of adult learner attrition.

Another future research direction is that of studying factors which affect the academic success rate of women, particularly single mothers, in online courses. The Institute for Women’s Policy Research has completed valuable research on the topic of college affordability for low-income adult learners. The work of this policy group should be supported and continued.

CONCLUSION

In the political arena, debate continues on the affordability of higher education in the United States. For students in many other economically

advanced countries, such those discussed in this chapter, New Zealand and Greece, national legislation results in the reduction of much of the cost of public higher education. But in the United States, policies on the national and institutional levels are especially needed to support the efforts of economically disadvantaged adult students who are at greatest risk of not completing their educational programs. Rising levels of adult student debt for online courses relate to the increasing attrition of mature learners in distance education programs in the United States. Although there has been recent litigation in California on the mismanagement of online student tuition and recruitment practices (Jackson, 2015), much more needs to be done to ensure that institutions of higher education which offer distance education programs are successful in meeting the academic and financial needs of all students.

Colleges and universities which offer online courses should act more honestly and effectively at not only fair practices in student recruitment and in financial assistance, but also in focusing those policies on accommodating the needs of adult students. Prospective students who are over twenty-five, many of whom are working single mothers, desire to further their education through online courses because they can conveniently access them anytime, anywhere (Garland, 2015). But, these underserved adults are among the most likely to drop out of online courses (Donnelly and Kovacich, 2014). According to Gast (2013), institutions should be marketing their distance education courses with adults in mind, supporting non-traditional students with specialized services, preparing mature students for post-degree or post-certificate professional work, and making their tuition more affordable. Higher education leaders should be more proactive in developing tutoring programs, offering financial and childcare services, and providing advisors who are sensitive to the needs of prospective or enrolled adult students.

Online instructors themselves can do much to design and implement online courses that are

meaningful to the adult learner. The collaborative efforts of both online teachers and their motivated, technology trained students are needed for adult learners like Rosa to transition from “digital exclusion” to “digital inclusion.”

From Digital Natives to Student Experiences With Technology

Sue Bennett

University of Wollongong, Australia

Linda Corrin

University of Melbourne, Australia

INTRODUCTION

The term ‘digital native’ was popularized by Prensky (2001) as a means to distinguish young people who were highly technologically literate and engaged. A ‘digital native’ can be defined as an individual who has grown up immersed in digital technology and is technologically adept and interested. The digital native is described in direct contrast to the ‘digital immigrant’, who having been exposed to digital technology later in life is fearful of it, mistrustful and lacks the skills to use technology adeptly. According to Prensky’s (2001) vision, all young people who have grown up since the widespread advent of the personal computer can be considered digital natives, and, by elimination, all older people are digital immigrants.

It is argued that the existence of the digital native makes dramatic educational reforms necessary because traditional education systems do not, and can not, cater for the needs and interests of young people. As a result, outdated schools and universities and outmoded teaching simply alienate students from learning, leaving them disengaged and disenchanted by education’s alleged failure to adapt to the new digital world. By implication, education must be transformed by technology, coupled with new pedagogies. Although this argument is a familiar one to those acquainted with the broader educational technology literature, the digital native hypothesis provides a new basis

for claims for revolutionary educational change through technology integration.

Recent research has revealed that the term is misapplied when used to generalized about an entire generation, and instead indicates that only a small sub-set of the population fits this characterization. This research shows significant diversity in the technology skills, knowledge and interest of young people, and suggests that there are important ‘digital divides’ which are ignored by the digital native concept.

This chapter charts the development of the digital native idea and the debate that has surrounded it. It provides an account of the research and conceptual work it has stimulated, and suggests future directions research may take in the coming decades.

BACKGROUND

The idea of the digital native appears to have first emerged in an essay entitled *Declaration of the Independence of Cyberspace* by Barlow (1995) in which he admonished parents with the charge: “You are terrified of your own children, since they are natives in a world where you will always be immigrants” (p.12). Papert (1996), in *The Connected Family*, similarly evokes a rift between parents and children, and teachers and students, portraying older generations as being both afraid of computers and technically incompetent. Clearly,

the idea of a digital generation gap was gaining currency at this time.

Regardless of its exact provenance, it has been Prensky who popularized the term 'digital native' in his widely cited 2001 article, *Digital Natives, Digital Immigrants*. Around the same time, Tapscott (1998) had put forward the similar notion of 'the Net Generation', while social commentators coined the term 'Millennials' as a generational label (Howe & Strauss, 2000). Since then a proliferation of less widely used epithets has appeared, all attempting to capture the essence of the same phenomenon (e.g., Generation C, Google Generation, Nintendo Generation, etc.).

In short, the idea of the digital native captured the imaginations of teachers, parents, journalists, commentators and academics. Closer examination of Prensky's arguments, particularly in his influential 2001 paper, reveals little in way of evidence to substantiate his claims, however. He relies on anecdotes, conjecture and speculation. Nonetheless his ideas have often been uncritically repeated and cited as if fact. Similar arguments purportedly based on evidence provide few details of the data collection methods and analysis processes, thwarting critical scrutiny of these studies (e.g., Tapscott, 1998; Palfrey & Gasser, 2008). This presents a significant challenge in assessing the quality of this research.

It was a few years after Prensky's 2001 paper before researchers began to seriously address his claims, apparently galvanized by dissatisfaction with his arguments. Since that time a significant body of international research has largely debunked the idea of a uniformly technically savvy generation. Instead it suggests that the label 'digital native' likely only applies to a small minority of the population. Of much greater interest is the wide diversity of technology use uncovered by this research. These differences are often thought of as 'digital divides' because they highlight significant gaps between the ways individuals and/or communities engage with technology. These gaps present an ongoing challenge to those con-

cerned with equity and justice in education, and in society more broadly.

More recently there have been attempts to redefine and rehabilitate the term 'digital native'. In fact, this emerged in Dede's (2005) argument that aptitude with technology is not necessarily related to age but to other personal characteristics. In recent years Prensky (2009) has also seemed to resile from his earlier sharp distinctions, praising rather than criticizing the role of the teacher. Nevertheless the original divisive idea remains potent.

In the next section we turn to examine some of the research evidence that has emerged in response to the idea of the digital native.

RESEARCHING 'DIGITAL NATIVES'

Researching Technology Use

In the mid 2000s researchers began to investigate some of Prensky's key claims about digital natives. The initial area of focus was on determining whether, in fact, digital technologies were as extensively used within younger generations of the population as was supposed by the digital native thesis (e.g. Kennedy, Krause, Judd, Churchward & Gray, 2006; Kvavik, Caruso & Morgan, 2004; Oliver & Goerke, 2007). These studies set about to establish the extent of access to and ownership of a wide range of technologies, and to discover the extent to which they were used for particular activities. In short, researchers wanted to know who was using what technology, how often and for what purposes. Similar research had already been conducted, for example through studies of children's use of technology in and out of school (e.g., Downes, 2002; Kent & Facer, 2004; Kerauwalla & Crook, 2002), but these studies were not specifically driven by the digital native concept. Related work was also being conducted in disciplines outside of education, such as youth studies, cultural studies and media studies, but again these did not relate to the digital native idea (e.g.,

Livingstone & Helsper, 2007; Selwyn, 2003). These studies do, however, suggest that there was a broader appeal to research along these lines.

Early ‘digital natives’ studies tended to use survey methods to collect data from large populations, often of higher education students. In this exploratory work researchers attempted to gain a broad perspective by collecting data from participants who are relatively easy to access with a focus on phenomena relatively easy to measure through self-report (e.g., Kennedy et al, 2006; Kvavik, Caruso & Morgan, 2004). While questions about access to technologies and frequency of use are common features of these studies, many have gone further to gauge skills, interests and preferences, have included multiple age ranges rather than only younger people, and in some cases incorporated qualitative methods to complement quantitative data. One of the most notable surveys has been the ECAR series in the United States, which has run since 2004 with consistently large sample sizes of college students (see Dahlstrom, Brooks, Grajek & Reeves, 2015 for the latest report). Similar studies from around the world have contributed to a developing understanding of technology use, particularly among young people (e.g., Jones, Ramanaua, Cross & Healing, 2010; Kennedy et al., 2009; Oliver & Goerke, 2007; Corrin, Lockyer & Bennett, 2010; Margaryan, Littlejohn & Vojt, 2011; Thompson, 2013; Teo, 2015; Akçayır, Dündar & Akçayır, 2016; Henderson, Finger & Selwyn, 2016; Šorgo, Bartol, Dolničar & Boh Podgornik, 2016).

In sum, the main findings of these studies have been as follows:

1. There is near universal adoption of some technologies (e.g., mobile phones).
2. Some technologies have not been widely adopted, for example, RSS feeds and some forms of social media. The reasons for this are not clear, however. Perhaps, some technologies are too specialized, overly technical, or judged to be less useful.
3. There are indicators of some differences due to age, gender, socio-economic background, year level of study, and discipline of study (at university or college), although findings are not consistent across all studies or all technologies.
4. The studies trace how some technologies are abandoned, for example, because they are superseded in favor of alternatives (e.g., the demise of MySpace and the rise of Facebook, and the shift from dial-up to broadband Internet access).
5. Skills, knowledge and interests are highly varied when comparing individuals. Findings suggest that individuals adapt their technology use to suit their needs and interests and the contexts they engage in.
6. Younger people often have lower skill and knowledge levels than what might be expected based on the digital native hypothesis.

A common conclusion from these studies is that, while there appear to be some age-related factors, diversity is often higher within age groups than between them. It is also important to note that while large-scale survey studies can indicate patterns, the measures used are relatively crude and their accuracy is limited by participants’ abilities to recall and estimate their usage. There is a need for qualitative studies that are capable of exploring technology use in greater depth and with sensitivity to individuals’ contexts. There are also, to date, few studies from developing countries and of less affluent communities, making the global situation difficult to discern.

In short, the research conducted thus far suggests that only a small minority of the population can be considered ‘digital natives’, even disregarding age as a factor to include technologically adept older people. People adopt technologies for a wide range of reasons and have diverse patterns and habits, and the skills they develop are often narrow and highly contextualized (i.e., fit for a particular purpose). As a result, it would be wrong

to generalize about a section of a population on the basis of how they use technology, and in particular on the basis of presumed exposure to technology.

Implications for Education

Prensky (2001) posed the problem for contemporary education as follows: “Our students have changed radically. Today’s students are no longer the people our educational system was designed to teach” (p. 1). This pronouncement was based on the assumption that all young people were digital natives being held back by an outdated education system. If, however, not all young people are digital natives, only some, and there is significant diversity within the population with regard to technological prowess, then the problem for education is somewhat different. The challenge of how education can cater appropriately for learners remains, but it is made more complicated by the fact that learners comprise a diverse rather than homogenous group. A further challenge for public education is that if some students are disadvantaged by virtue of their socio-economic situations, then how can an inclusive education system address that disadvantage?

Concerns about a digital divide between the ‘haves’ and ‘have nots’ first emerged in relation to differences in access to technology (Warschauer, 2004). As technology became cheaper and easier for ordinary people to obtain, the focus shifted to differences in the skills and knowledge people have to make effective use of technology (Selwyn, 2004; Warschauer, 2004). And as ideas about what it means to be digitally literate have changed, this has seen a move away from a focus on developing people’s technical skills to a focus on developing their capacities to use technology responsibly, creatively and innovatively. This poses questions for education about how students can be equipped with these more sophisticated skills and understandings.

The infusion of digital technologies into everyday life has also raised questions about the relation between technology in education and out,

particularly amongst those who speculate about how the high levels of motivation exhibited by young people while gaming or socializing online might be employed in learning (Prensky, 2001; Tapscott, 1999). This reflects a wider conversation about how Web 2.0 technologies might be integrated into education, and warnings that their application might not be straightforward because of fundamental differences between informal learning and formal educational contexts (Dohn, 2009).

These discussions indicate that while the original digital native hypothesis is not a sound basis for recommending or planning educational change, differences in the ways technologies are used and their increasing prevalence in society continue to raise important questions for education. These are questions that need to be informed not only by empirical evidence gleaned from further research studies, but also by theories that help us to explain the phenomena and thereby better understand it.

Theoretical Perspectives

Just as the original proposal of the digital native lacked empirical foundations, theoretical underpinnings were also absent. However, as the research agenda has developed, casting doubt on the general nature of the claims and in doing so revealing people’s diverse engagements with technology, researchers have begun to conceptualize both the nature of the debate itself and to propose theoretical constructs that might help to explain the phenomena and frame future investigations.

The debate itself has been described as an academic form of a ‘moral panic’, a concept widely used in the social sciences (Bennett, Maton & Kervin, 2008). A moral panic, as described by Cohen (1972), occurs when a particular group is seen as a threat to societal norms. Importantly, the concern inspired exceeds the supporting evidence. Thus, the lack of evidence base and the extreme language used in arguments for the existence and importance of digital natives is consistent with a

moral panic. This characterization is useful because it helps to explain how the idea gained such prominence on the basis of flimsy evidence. It also explains how the form for the debate stymied genuine academic discussion until the emergence of empirical research.

More recently, researchers have proposed that this empirical evidence provide the stimulus for developing more sophisticated ways of thinking about and researching people's technology use (e.g., Bennett & Maton, 2010). Drawing on a range of sociological theories, these authors argue that concepts related to social networks (Castells, 2001; Wellman, 2002), social practices (Bourdieu, 1990) and the nature of knowledge and education (Bernstein, 1999) are critical to advancing understanding in this area.

SOLUTIONS AND RECOMMENDATIONS

Although research on young people's use of technology has consistently found diversity in areas such as access, use and ability with technology, there are several ways educators can address these differences within educational environments. In acknowledging that diversity exists, educators and institutions should be encouraged to investigate the profile of students in their own context. Such understandings can inform effective design of technology-based activities and how best to articulate these to students. This includes making clear the purpose and value of using particular technologies in the context of learning activities (So, Choi, Lim & Xiong, 2012). At an institutional level, caution should be exercised when setting strategy and targets around levels of use of technology to avoid the use of technology for technology's sake.

While the digital native concept emphasizes the high levels of engagement with technology in young people's everyday lives, research has revealed much lower levels of adaption of these technologies to support learning. The technology

choices of young people to support their studies tend to focus on pragmatic functions like speed, convenience, and efficiency (Henderson, Selwyn, Finger & Aston, 2015; Thompson, 2013). Questions have also been raised about whether young people have the requisite pedagogical knowledge to inform innovative technology choices to support their learning (Margaryan et al., 2011). Consequently, assumptions cannot be made that young people will have the knowledge and skills to be able to adapt and use a wide range of technology in an educational context. As a result, educators have an important role to play in influencing and stimulating young people's engagement with technology (Henderson, Finger & Selwyn, 2016). In order to do this, educators need support to develop their own digital literacy (Ng, 2012).

Greater attention regarding enhancing digital literacy for young people in the context of education is required. Despite the increasing trend in young people's exposure to and ownership of technology, ownership of technological devices alone does not directly impact levels of digital literacy (Šorgo, Bartol, Dolničar & Boh Podgornik, 2016). Recommendations from recent research consistently call for increased support for digital literacy in learning environments broadly, but also specifically within the context of particular learning activities (Buzzard et al., 2011; Toliver, 2011; Thompson, 2013). The form, timing, and extent of this support needs to be customized to the specific context, but also be flexible enough to cater for the diverse experiences and skills of the audience.

FUTURE RESEARCH DIRECTIONS

Future research into people's technology uses and choices will continue to monitor new developments, sparked by emerging technologies and changing patterns of adoption and use. In the short term, one focus will be on the impact of Web 2.0 technologies and their proposed capacity for democratizing participation in technology-based

activities. More generally, the trend towards greater online connectivity through new services and devices will continue, and so pose further questions for researchers about digital divides and digital inclusion across societies. The role technology plays in supporting learning that happens in formal and informal educational contexts is another area of research that will provide insights that can inform design of learning activities and technology support.

Future research will also require a commitment to developing more sophisticated understandings of technology use and choice. As noted above, in-depth qualitative research will be needed to provide insights into the diversity uncovered by recent surveys. Longitudinal studies that observe students' technology choices over time are also needed to understand the factors that influence changes in interaction and transitions between technologies (Corrin, Bennett & Lockyer, 2013; Henderson, Finger & Selwyn, 2016). Findings from this work will enable the field to transcend simplistic labels and thereby truly account for the rich array of activities and practices with technology. These are developments that can underpin discussions about what role technology can and should play in education such that the best learning outcomes can be achieved for all students.

CONCLUSION

To conclude, although misguided in its attempt to characterize a whole generation of young people, the idea of the digital native has been helpful in drawing educators' and researchers' attention to the under-researched area of young people's technological experiences and preferences. It has stimulated a very productive and promising avenue for educational technology research that has the potential to lead to better informed decision-making about technology and to improved teaching and learning. The challenge for educators moving forward is to develop ways to

make effective use of technology in teaching and learning while acknowledging and addressing issues around students' diversity in technology use and ability. This requires sophisticated thinking and careful consideration (Bennett & Maton, 2011) of the role of technology in teaching and learning that moves beyond a reliance on simplistic, generational labelling.

KEY TERMS AND DEFINITIONS

Digital Divide: Digital divides are gaps between individuals or groups due to differences in their access to digital technologies. Access

refers to more than physical access, including also the ability to use technologies effectively. Divisions may occur due to factors such as age, gender, race/ethnicity, socio-economic status and/or geographic location.

Digital Generation Gap: The digital generation gap refers to the proposed gap between children and adults (especially parents and teachers) due to young people's natural ability to adapt to new technologies more successfully than older generations.

Digital Immigrant: A digital immigrant is a person born before the widespread adoption of computers and has had to adopt digital technology later in life. Digital immigrants are considered to be less technically able than digital natives and it is argued that they can never develop the same level of technology skills and knowledge as digital natives.

Digital Inclusion: Digital inclusion refers to mindsets, strategies and initiatives that seek to ensure that all people in society have equitable access to technology regardless of their personal circumstances. It is underpinned by the belief that access to technology and the ability to use it effectively are important to citizenship and social cohesion.

Digital Native: In its original sense, a digital native is a person who has grown up after the widespread introduction of the personal computer and therefore been immersed in digital technology. It is claimed that by virtue of this exposure digital natives think, behave and learn differently to older generations. More recently the term has been redefined by some to refer to a person of any age who is highly adept with technology.

ICT Eases Inclusion in Education

E**Dražena Gašpar***University of Mostar, Bosnia and Herzegovina*

INTRODUCTION

Access to education was defined as a fundamental human right in the framework of the Declaration on the Human Rights from 1948. However, the World Report on Disability written in 2011 by the World Health Organization and the World Bank estimates that there are between 93 and 150 million school-aged children with disabilities around the world (UNESCO, 2014). Unfortunately, the fact is that many of these children are completely excluded from educational opportunities, even primary education. Also, because of their learning difficulties, great numbers of children do not have equal access to education.

The inclusion of children with special needs in regular classes creates an entire range of challenges within a given school system and requires the application of new methods and forms of work that are appropriate to each child.

Information and Communication Technologies (ICT) should be increasingly involved in the educational system to improve the quality of teaching, and to provide new experiences during the teaching and learning processes. In this paper term ICT covers all the technologies used to communicate, create, store and manage information. With use of ICT it becomes possible to meet the specific needs of different groups of students, including students with special needs. For students with special needs, ICT can offer numerous ways to remove obstacles as they try to participate in the teaching and learning of the curriculum.

This chapter presents brief analyses of different supportive technologies, such as hardware and software solutions, Web 2.0 technologies, virtual learning environments (VLEs), virtual

worlds, and other similar technologies. The aim of this chapter is to show the potential of ICT in education, especially when facilitating student inclusion. This chapter will also stress some open issues, including limitations in interactions, communication, and learning. ICT can provide new opportunities in inclusive education, and despite all of its potential limitations, ICT should be considered as a key tool to promote equity in educational opportunities.

BACKGROUND

In this paper, the definition of inclusive education, as set out by UNESCO, is adopted: *Inclusive education is a process of strengthening the capacity of the education system to reach out to all learners... As an overall principle, it should guide all education policies and practices, starting from the fact that education is a basic human right and the foundation for a more just and equal society* (UNESCO, 2014, p.11). Coupled with the process of inclusion, the term “special educational needs” (SEN) is often used across Europe. This term is frequently adopted to specify *learners who encounter barriers to learning, either temporarily or in the long term* (EADSNE, 2013, p.6). This definition stresses that the term SEN covers not just learners with disabilities, but all learners who, for various reasons, do not make expected progress for their age. According to this concept, learners with SEN comprise a wider group of students than those with disabilities alone and there are some estimates that these individuals account for around 20% of the school-age population (EADSNE, 2013, p.6).

DOI: 10.4018/978-1-5225-2255-3.ch220

ICTs that are used to support children, young people, and adults with disabilities, are commonly referred to as assistive technologies (AT), although there is no one single internationally accepted definition for this term. The British Assistive Technology Association (BATA), a social enterprise that focuses on AT for inclusion in education, defines AT as *any item, equipment, hardware, software, product or service which maintains, increases or improves the functional capabilities of individuals of any age, especially those with disabilities, and enables them more easily to communicate, learn, enjoy and live better, more independent lives* (BATA, 2015, para.2). In this chapter, the BATA definition of AT is used.

Research into assistive learning technologies has grown significantly in the last decade. Today, research into specific topics can be found in many books and journals worldwide and is the focus of many specialist publications from a variety of disciplines. As such, including all research related to ICT – or, more precisely, to AT – in this short review is in the advance lost battle. Therefore, this review should be understood simply as the author’s own choice of sources related to research on ICT in inclusive education, mostly from last five years.

Recent researches have shown that ICT, in its various forms, is decreasing the gap in education and enabling the inclusion of students with special educational needs in classrooms with their classmates; furthermore, AT help students largely reach their educational goals (Brodin, 2010). Several studies point to the idea that ICT could help SEN students, particularly students with reading and/or writing disabilities, through word processors, word prediction programs, spell and grammar checks, voice recognition, text-to-speech (TTS) programs, planning and organizing tools, etc. (Anderson et al., 2009; Maor et al., 2011; Peterson-Karlan, 2011).

Also, a number of studies have shown that all teachers should be familiar with the use of ICT for SEN students because students who benefit from ICT can be found in every classroom (Anderson et al., 2009; Starcic, 2010). According to the parents in Brodin’s (2010) study, ICT was

used only to a limited extent, and they complained about the teacher’s lack of knowledge about ICT use and tools.

In the last few years, the term “accessible technology” has been adopted to define technologies designed to allow learners to use mainstream technology without any disadvantages, as opposed to AT, which specifically support SEN learners (Barres et al., 2013; McKnight & Davies, 2012). Of course, between those two technologies, considerable overlap exists. Namely, ICT developers apply inclusive design approaches, so their technology can be used instead of AT; using *methods designed to make technologies or information accessible, therefore may be counted as assistive technology approaches, as the approach is assistive, even if the technology is not necessarily so* (McKnight & Davies, 2012, p.13).

ICT SUPPORT FOR INCLUSIVE EDUCATION

The implementation of inclusive education within the regular school system involves a number of activities that take place throughout the entire school practice of all of its participants. The inclusion of children with special needs in regular classes requires the application of new methods and forms of work appropriate to each child (Gašpar & Vetma, 2014). This process is, by itself, very complex and its results are usually not instantly visible. ICT support could ease that process for all stakeholders and make the results more visible. When inclusive education is in question, all aspects of the use of ICT become important. ICT could provide SEN students with the following key inclusive benefits (Winter & O’Raw, 2010, p.87):

- Better control over their own learning experience.
- Students can participate and contribute more fully in classroom activities, and they can also complete assignments independently.

- Students can interact, to a greater extent, with their typical peers, ultimately improving their social skills and enhancing their acceptance.

ICT Classifications

There are different approaches and classifications about what inclusive ICTs in education comprise. The reason for this lies in the fact that ICTs/ATs are very diverse, numerous, and are constantly undergoing change. In one of its documents, UNESCO recognized that inclusive ICTs for education include (UNESCO, 2014, p.11):

- **Mainstream Technologies:** Commercial products available in the market and dedicated to all individuals (computers, Web browsers, word processors, whiteboards, mobile phones and etc.).
- **Assistive Technologies:** Specific technologies that enable SEN learners to access and use mainstream technologies (medical aids, learning aids such as screen readers, alternative keyboards, augmentative and alternative communication devices, and etc.).
- Compatibility between AT products and mainstream technologies.
- Accessible media and formats, such as mainstream publication formats (MS Word, PowerPoint, and structured and tagged PDF files) or HTML5 (Hypertext Markup Language), videos with captioning, DAISY (Digital Accessible Information System) books, EPUB, etc.
- Accessible digital learning content and instructional delivery systems, such as those found in online learning environments, in the classroom, or in learners' management systems.

However, there are other approaches, like the ones used at LEARN (Leading English Education and Resource Network), a non-profit organiza-

tion that primarily serves the public and private Anglophone and Aboriginal Youth and Adult education sectors of Québec, Canada (LEARN, 2013). LEARN organized learning aid in two main groups: computer and peripherals and learning and communication aid. A different approach is used by Futurelab at NFER – the National Foundation for Educational Research in the United Kingdom (FUTURELAB, 2009). Futurelab organized AT in six categories: mobile technologies, audiovisual tools, online communities, podcasts, blogs, wikis, games and learning platforms.

The focus of this chapter is primarily on specific the ICT used for inclusion education (AT), rather than on the general accessibility of mainstream ICT, especially when hardware and software programs are in question. The currently developed AT classification follows the main chapter's idea and comprises three main types of AT:

- AT based on hardware solutions,
- AT based on software solutions, and
- AT based on Web technologies.

Hardware AT solutions are comprised of devices that ease one's access to a computer (PC or laptop), such as substitutes to the standard keyboard (ergonomic keyboard, keyboard with large keys, pen-touch keyboard, adjustable keyboard, touchless keyboard, left-handed/one-handed keyboard, Braille keyboard, voice-activated keyboard, illuminated keypad, etc.), a substitute to a standard screen (cursor/pointer tracking, screen reader – Braille, and speech synthesizer, etc.), or a substitute to a standard mouse (trackball, switches, mouth-activated pointing device, foot-activated pointing device, head- or eye-activated pointing device, voice-activated control device, touch screen, mouse emulator, etc.). Also, hardware AT solutions include other devices (tablet, mobile phone, digital camera, scanners, text [Optical Character Recognition, or OCR] scanner, barcode scanner with synthesized voice, devices with symbol-based communication, and TTS output, etc.) that could be used as input devices or for data capture and

communication support to an adapted learning environment. For example, OCR is a method of converting text from paper format to an electronic version, usually by using a scanner. Accordingly, books, printed worksheets, even photographs with graphics and text can be converted to digital form and read aloud using TTS.

Software AT solutions are comprised of software-enabling oral/written communication (word processors, voice recognition, TTS, word prediction, etc.), remote communication software (e-mail software with icons), software support for specific subjects (spelling/grammar check, dictionary, visual dictionary, digital calculator, digital microscope, digital encyclopedia, notation software for music, sequencer music software, synthesizer, paint or image editing software), and software support for planning and organizing (graphics organizers, electronic agenda, digital portfolio, etc). For instance, some of the built-in features in standard word processing software can support students who have difficulty with written language and processing. For example, spell check helps students with dysgraphia and other learning disabilities. Also, the autocorrect feature can be enabled or disabled depending on students' strengths and needs. Grammar check helps students identify awkward grammatical constructions like passive sentences. TTS add-ins support auditory proofing before students submit their work, while numerous free TTS add-ins for Microsoft Word are also available (Hobgood & Ormsby, 2014).

Web technologies that could be used in inclusive education are comprised of social networks (Facebook, Twitter, LinkedIn, etc.), Website creation tools (blogs, wikis, etc.), collaborative tools (virtual learning environments), three-dimensional (3D) tools (virtual worlds, virtual touch, etc.), audio tools (audio creating, audio sharing, etc.), video tools (video creating, video sharing, video streaming, etc.), text-based tools (note-taking and document creating software, discussion forums, etc.), and image-based tools (image sharing, online whiteboards, drawing tools,

etc.). Web-based systems provide opportunities for young people to access multimedia-rich resources, which can support SEN learners, and also provide a richer learning experience for all. For instance, for students who do well with written products, online text platforms like blogs and wikis can increase motivation by offering the promise of an attractive product with a "real" audience. Some blogging sites offer teachers the ability to create a classroom blog linked to individual student blogs (Hobgood & Ormsby, 2014).

Virtual Learning Environment

A Virtual Learning Environment (VLE), also known as Course Management Systems (CMS) or Learning Management Systems (LMS), is a system through which learning materials are delivered to students via the Web. These systems include assessment, student tracking, collaboration, and communication tools (OXFORD ORC, 2015). These environments also offer students access wherever they are, 24 hours a day, 7 days a week, 365 days a year. Because of that, educational institutions can offer lessons not only to full-time students, but also to workers studying part time.

There are different types of VLE and they fit into any one of the following three categories (OXFORD ORC, 2015, para.2):

- Off-the-shelf environments, such as Blackboard or WebCT.
- Open source environments (often free to use and adapt, but where support is charged for), such as Moodle. Figure 1 is an example of a Moodle screen.
- Bespoke (developed by institutions for their own individual needs).

Virtual World

A virtual world is a computer-based, online community environment that is designed and shared by individuals so that they can interact in a custom-built, simulated world. Today, users interact in

Figure 1. Example of a Moodle screen (MOODLE, 2015)

Source: Moodle, 2015.

the virtual world using graphical models called avatars. Avatars are controlled using input devices (keyboard, mouse, and other specially designed simulation gadgets). All virtual worlds possess the qualities of persistence and interactivity. This enables the users to explore the inherent benefits of socialization and allows them to study human nature and users' abilities (TECHOPEDIA, 2015).

The educational activities that can be carried out in a virtual world are quite diverse (Dalgarno & Lee, 2012, p.241):

- Exploration (simulation of a library, school, or church).
- Practicing with theoretical concepts through interaction (with other avatars or with objects in simulated locations).
- Carrying out activities that are difficult to perform in the real world, either for their difficult implementation or dangerousness (e.g., simulation of a medical intervention, handling chemicals).
- "Role playing" activities, assigning different roles to each student.
- Playing serious games, in which the student learns in a playful way.

Some of the popular virtual worlds are: Second Life, OpenSim, Unity, and Active Worlds.

One example of the use of a virtual world in education is the "Accessibility in Virtual Worlds" project, which is aimed at blind students, whose positions are indicated by sounds, thus enabling navigation and interaction with peers, both blind and sighted (Sheehy, 2010). Another example that uses virtual worlds for inclusion is Brigadoon. It is an island in Second Life that serves as a therapeutic place for people with Asperger syndrome (autism); it facilitates these students' social interactions by using avatars in a controlled environment (Biever, 2007). Figure 2 is an example of a Second Life screen.

SOLUTIONS AND RECOMMENDATIONS

The process of implementing ICT in inclusive education is very complex, resource consuming (specifically of people, time, and material resources), and it does not always feature clearly visible and measurable results. The latest OECD PISA (Program for International Student Assessment)

Figure 2. Example of a Second Life screen
(Second Life, 2015).
Source: Second Life, 2015.

report issued on September 15, 2015 says that even countries which have invested heavily in information and communication technologies (ICT) for education have seen no noticeable improvement in their performances in PISA results for reading, mathematics or science (OECD, 2015a, para.2). Conversely, although only 42% of 15-year-old students in Korea and 38% in Shanghai–China stated that they used computers at schools, students in both Korea and Shanghai–China were among the top performers in digital reading and computer-based mathematics tests in the OECD PISA in 2012. On the other hand, in countries where students demonstrated more Internet use at school for schoolwork, students’ performance in reading generally declined between 2000 and 2012 (OECD, 2015b, p.15). The results of the OECD PISA report show that ICTs have not yet been widely adopted in formal education. *But, where they are used in the classroom, their impact on student performance is mixed, at best. In fact, PISA results show no appreciable improvements in student achievement in reading, mathematics or science in the countries that had invested heavily in ICT for education* (OECD, 2015b, p.15).

One of the possible interpretations of these findings could be that educators need additional time and effort to learn how to use ICT in the classroom

and, at the same time, they need to stay focused on student learning. Because of that, the PISA report results should not be interpreted in such a way that investment in and implementation of ICTs in education should be stopped. On the contrary, these results point to the need for critical thinking about how to implement and integrate ICTs in education, particularly in inclusive education.

Although in most countries, gaps in computer access between advantaged and disadvantaged students has lessened between 2009 and 2012, the results from the PISA report show that *once the so-called “first digital divide” (access to computers) is bridged, the remaining difference between socio-economic groups, in the ability to use ICT tools for learning is largely explained by the difference observed in more traditional academic abilities* (OECD, 2015b, p.16). The conclusion is that in order to create equal opportunities in the digital world, it is better to ensure that all learners achieve a basic level of proficiency in reading and mathematics than to get expanded access to high technology (OECD, 2015b, p.16).

It is obvious that relationships between learners, ICT, and the learning process are very complex and loose, so any real contributions that the ICT could make to teaching and learning have yet to be fully researched.

There are a lot of open issues related to the process of ICT implementation in inclusive education, such as:

- How to ensure full engagement, dedication, and participation of all relevant stakeholders (governments, teachers, [SEN] learners, parents...).
- How to ensure full cross-sectorial and intergovernmental agency cooperation and coordination.
- How to avoid harmful aspects of Internet use (information overload, plagiarism, fraud, violations of privacy, online bullying, etc.).
- Development, implementation, and monitoring of realistic strategies related to ICTs in inclusive education.
- Overestimation of digital skills among learners, teachers, and parents.
- Hidden resistance of teachers, learners, and parents (everyone supports innovation, but not in his/her school and not for his/her children).
- The benefits of “good practice” cases are mostly insufficient to mobilize support (the costs for “bad practice” are concentrated).
- The relatively low quality of educational software and courseware.
- The loose standards in developing educational software and courseware.

Some of the recommendations for coping with the listed issues are as follows:

- Previous experiences with the implementation of ICTs in inclusive education, whether good or bad, should be something to learn from.
- The government should have to ensure the framework for successful implementation of ICT in inclusive education. That framework includes appropriate policy documents (strategies, action plans, etc.) developed in coordination with all rel-

evant stakeholders (governments, ministries, agencies, teachers, parents, etc.). Also, government responsibility includes developing adequate ICT infrastructure (especially communication infrastructure, such as providing broadband access to the Internet), additional support to educate teachers and parents about ICT in inclusive education, and enabling access to information about available ICT tools and standards (Websites).

- The foundation skills necessary for the digital age should be taught, and not always with the use of ICT.
- Teachers have to become not just leaders in the implementation of ICTs in inclusive education, but also equal partners in their design.
- Teachers are crucial in ensuring the successful exploitation of ICT in inclusive education, but they require education and training to equip them to succeed.
- Teachers should combine their efforts and experience to improve /develop teaching and learning methodologies featuring fully integrated ICT.
- ICT should support the teaching and learning process. The focus of teachers should be on learners, teaching, and learning methods.

ICT can be a valuable tool for SEN learners who are more vulnerable to the digital divide and to exclusion from educational opportunities. If ICT is implemented and integrated into teaching and learning processes in an appropriate way, ICT can improve students' quality of life by increasing their participation and reducing social exclusion.

FUTURE RESEARCH DIRECTIONS

Further research related to ICT in inclusive education should be focused on the following directions:

- Forming interdisciplinary teams composed of teachers, learners, parents, ICT professionals, pedagogues, psychologists, etc., in designing and developing inclusive ICT tools.
- Forming interdisciplinary teams composed of teachers, learners, parents, ICT professionals, pedagogues, psychologists, etc. in developing new and improving existing teaching and learning methods.
- Forming interdisciplinary teams composed of teachers, learners, parents, ICT professionals, pedagogues, psychologists, etc. in developing and implementing standards for inclusive ICT.
- Research the use of tablet and mobile phones in inclusive education.
- Research new methods of interaction with ICT, which are achieved by body gestures, eye movement, and via the brain and nervous system.

CONCLUSION

This chapter briefly described the types of technologies used, and the ways in which they can be used, in inclusive education. Although all aspects of the use of ICT are important, many researchers have observed the importance of how ICT is applied – meaning how it is integrated with teaching methodologies. All past experiences of ICT implementation in inclusive education have demonstrated that providing the technology itself is not enough. Teachers are essential in that process, but they require additional education and training, as well as more information on how to choose appropriate ICT tools. Namely, the use of ICT in inclusion is a lifelong requirement that extends beyond the classroom. Some learners require that information is provided in a form that they can easily understand (in an easy-to-read or symbol format), or on an accessible Website that can be read aloud using screen-reading technology. Other

students might need a device that speaks, and thus supports communication and social interaction. By allowing users to learn at their own pace, ICT can also encourage less able students while enhancing their self-confidence.

New ICT devices, like tablets and smart phones, as well as new methods of interacting with technology via body gestures, touch, eye movement, and even directly via the brain and nervous system, are providing new opportunities, as well as potential barriers, for interaction, communication, and learning, thus opening the door to new research opportunities. However, the general conclusion is that ICT should be considered as a key tool for promoting equity in educational opportunities, and that access to appropriate ICTs should be considered as an essential human right.

KEY TERMS AND DEFINITIONS

Assistive Technologies (AT): Information Communication Technologies that are used to support people with special needs.

Inclusive Education: Education tailored to the needs of each learner, regardless of her/his physical, intellectual, social or other conditions.

Information Communication Technologies (ICT): Term ICT covers all the technologies used to communicate, create, store and manage information, including computers, the Internet, broadcasting technologies and telephony.

Students With Special Needs (SEN): Learners with difficulties in learning, temporarily or permanently, that cause that they do not make expected progress in education for their age.

Virtual Learning Environments (VLEs): The specific form of educational system that includes tools for communication, collaboration, student tracking, assessment and so on, all based on Web platform.

Virtual World: Computer based simulation of real world where users can create a personal avatar which explore the virtual world, participate in its activities and communicate with other avatars.

Web Technologies: All technologies based on any effective computer network (Local Area Network, Wide Area Network) that make it possible for different computers to communicate and share resources.

The Infusion of Technology Within the Classroom Facilitates Students' Autonomy in Their Learning

Garry Soomarah

University of Trinidad and Tobago, Trinidad and Tobago

INTRODUCTION

The use of technology in education is not something new or innovative but rather an asset in assisting our students with their cognitive skills. Many people have argued that the benefit of technology infused into education is non-existent or even limited to have any significant impact to truly advocate its use in the mainstream curriculum. To have an impact, some (Niess, 2005; Shulman, 1986) suggest that in order for technology to become an integral component or tool for learning, science and mathematics pre-service teachers must develop an overarching conception of their subject matter with respect to technology and

what it means to teach with technology. Others (Hooper, 1991; Rieber & Welliver, 1989) state the full potential of any educational technology can only be realized when educators progress through five steps or phases: Familiarization, Utilization, Integration, Reorientation, and Evolution, otherwise, the technology will likely be misused or discarded. It is further stated that the traditional perspective of educational technology focuses on either the technology itself or a teacher's instruction which is only the first three phases as shown in Figure 1.

The motivation behind this experiment was to investigate if technology can be used to assist students to focus on constructing his/her own

Figure 1. A model of adoption of both "idea" and "product" technologies in education

Figure 2. Summary of CSEC maths pass rate (2009 – 2011)

CXC CSEC Pass Rates:			
Mathematics examination			
Average score for June examination			
Year	Total % students passing Paper 1	Total % students passing Paper 2	Total % students achieving a passing grade overall
2011	62%	17.5%	36%
2010	57%	24%	41%
2009	62%	26%	45%

knowledge without developing an overarching conception of their subject matter. The success of this experiment was determined by an improvement in the pass rate in teaching. Research was done in order to determine which teaching subject will be the subject of this experiment. Researchers have noted that many students entering university often fail 1st year mathematics which may be due to a poor mathematics background (Eng, Li Li, & Julaihi, 2009; Rylands, & Coady, 2009; Whannell, & Allen, 2012). In the Caribbean, there is also a general weakness in students' mathematics background as stated by a former deputy principal of the University of the West Indies, Mona campus (Green-Evans, 2005). Students who complete high school write an official examination from Caribbean Secondary Education Certificate (CSEC) in order to get accepted into a university. Figure 2 shows a table summarising the results of all the Caribbean high school students who wrote CSEC mathematics for 3 years. This performance re-enforce the fact that students have a weakness in mathematics, especially in paper 2, the written examination. Paper 1 is multiple choice examination (Caribexams, 2004).

Based on these findings, the subject chosen for the experiment was 1st year Mathematics at the University of Trinidad & Tobago (UTT). Technology was used to build a virtual classroom (VC) to

assist students with their cognitive skills ensuring that the subject matter in teaching mathematics did not require an overarching conception. Instead the VC and physical classroom was part of a blended approach. The VC provided an environment for students to focus on expressing their existing knowledge of mathematics, reflecting on this knowledge and thinking in order to provide prompt feedback. At the end of the experiment, students provided suggestions to enhance the VC which were considered and other VCs were designed.

BACKGROUND

The relatively recent introduction of new technology into mainstream schooling was widely expected to penetrate and transform teaching and learning across the curriculum. As noted by (Kinach, 2002), teacher educators must challenge their pre-service teachers' habitual ways of thinking about subject matter and subject matter teaching. This is especially important in the teaching of mathematics since for many years there has been increasing concerns about students failing achievement in mathematics and their negative attitudes towards mathematics, despite its importance in the 'world today' (Gresham, 2007). Some educators believe that students develop attitudes and

emotional reactions towards mathematics from as early as 9 years old (McLeod, 1992), which are seldom ambivalent; rather, they are either positive or negative, with negative attitudes persisting well into adulthood (Brady & Bowd, 2005). Research into the factors that impact upon students' success in, and attitudes towards mathematics point to mathematics anxiety as one of them (Shores & Shannon, 2007).

The aim of this project was to investigate whether infusing technology into education can advocate use in the mainstream due to an increase in pass rate. If there was an increase of the pass rate of 1st year mathematics, it suggests this approach had a positive impact in teaching and further work is required. The VC presented teaching matter through reflective questions emphasizing on background knowledge which focused on 9 years old students, e.g. fractions. The VC was designed so that it was free, accessible 24/7, fosters collaboration, anonymous and most importantly to ensure that students feel comfortable thus encouraging students to share their understanding and thoughts on a question. The students were given an incentive of 10% of final mark awarded based on the number of comments on the VC. For example, more than 150 comments was awarded 10%. Even though the students were extrinsically motivated into participating in the beginning for the marks, their attitude towards the VC changed in which they sought greater autonomy in the learning process. This drive towards autonomy was made possible because of the many benefits derived from using the VC such as the students took control of his/her learning which was demonstrated by student's frequent comments.

This VC provided an environment where students were able to share their thoughts without being ridiculed as well as learn at his/her own pace. Thus motivating students to build on whatever existing knowledge they had which according to Maslow (Huit, 2007) is achieved by satisfying their needs according to his hierarchal model. Based on his theory it is perceived that once ones

basic needs are met they are able to move on to the other level of development. Maslow's motivation theory suggest that an individual can only move up the pyramid based on the needs of the previous level being met or satisfied. Due to their needs being met, students' level of competency proportionally increased, therefore their self-efficacy in the given study increased. A contributing factor to this was anonymity which allowed everybody using the VC to share their thoughts. This allowed students to be bold and take risks in asking questions which otherwise may not have been asked thus the VC acted as a form of scaffolding.

Scaffolding acts as a stepping stone in which students build on previous knowledge before moving on to the next level. This is achieved when students are comfortable in sharing their existing level knowledge and building on it from their peers or instructor, who is an expert. According to Vygotsky (1978) scaffolding can act as a form of social and instructional support needed by students who are learning new material. After students have achieved understanding of the specific concept the scaffold is taken away so that they can move on to the next level. Vygotsky (1978) also spoke of the Zone of Proximal Development (ZPD) which he defined as the distance between the actual developmental level as determined by independent problem-solving and the level of potential development as determined through problem-solving under adult guidance, or in collaboration with more capable peers. The VC results suggest that based on the components of Vygotsky's (ZPD), the instructor's guided problem solving questions motivated the students to collaborate resulting in just over 2000 entries in one of the experiment. Hence they were able to move from Bloom's (1956) cognitive taxonomy of knowledge to that of analyzing, evaluating and creating which are higher order cognitive skills in the taxonomy. The improved understanding by the students will result in more students passing thereby increasing the pass rate.

DESIGN OF EXPERIMENTS

The experiment was designed to help students discover his/her current knowledge and then construct new knowledge by building on his/her existing knowledge. A VC was built as a support to the traditional classroom teaching using the blended approach. The sample was 1st year UTT students and all 68 students used the VC. The objective was to improve the students' understanding thereby improving the pass rate for UTT 1st year Mathematics for Technicians. The pass rate was 25 – 40%.

All students had to use the VC and some students wanted a choice. The 2nd VC was from 100 students who chose either VC or answer the questions on paper. The objective was to determine if the improvement to the pass rate for Mathematics for Technicians Level 1 was due to technology or not.

Students approached the instructor to use technology to teach without a physical classroom. This was the 3rd VC with 28 repeating students who were scheduled for classes 5:00 pm – 9:00 pm (difficulty in getting transport after 9:00 pm). The objective was to improve the pass rate for Mathematics for Technicians Level 1 regardless of the constraint of no traditional teaching.

Some students reoriented the VC and a new VC was evolved through them. The 4th VC was totally the students' idea and design. The objective was to allow students and instructor to guide the VC by the postings. Also social and entertaining postings such as videos and pictures were allowed. This VC had 100 students.

1ST VIRTUAL CLASSROOM

The 1st VC was designed to incorporate technology with learning mathematics by providing a classroom outside the physical classroom which was not affected in any way. The VC, a blog from blogger, was designed using Web 2.0 technology. All 68 students had to be registered anonymously

to this one blog. The anonymity promotes honest opinions as it combats fear of judgement and embarrassment of correction, thus these barriers which exist in a physical classroom no longer were limitations. A student was allowed to register as different users to create suspense and interest. The 68 students were all the 1st year Mechanical, Chemical & Petroleum engineering students. Each discipline was taught separately but by the same instructor and had a common final examination. As an incentive to encourage the students to make comments and post questions on the VC, 10% (of final mark) was awarded based on his/her VC usage. For example, more than 150 postings was awarded the full 10%.

The VC was guided by the instructor who posted questions hoping to engage the students in reflecting and making his/her comments. The comment displays the student current knowledge and can be an eye opener into background knowledge. Writing a comment will also have an additional benefit in providing an opportunity for a student to express his/her knowledge through writing thus enhancing writing skills. Some students understanding of the content lead them to provide feedback for other students' comments thus allowing that student to take the role of the instructor. The opportunity for a student to be the instructor motivates that student to continue using the VC. This is based on the work of Steinberg and Maslow (1943) who state the importance of motivation playing an integral part in educational development of student autonomy in their learning. An incorrect comment provided an opportunity for another student to analyse and rebuild that incorrect knowledge. This dialog thus breaks down the barriers between students and instructor thereby shifting the role of instructor. An example from 2 VC users, Lifesaver and Weezy, is shown in Figure 3.

Problem solving which is inherent in the study of mathematics has been demonstrated to strongly influence students' attitudes, both positive and negative (Debellis & Goldin, 2006; Hannula, 2002). The VC strived to portray a positive outlook

Figure 3. Dialog between students

in an attempt to connect to the individual level each student was at. Students were encouraged in the physical classroom to use the VC by assuring them prompt feedback. The instructor was registered as a very unintelligent student asking a lot of questions. This provided an avenue for students to think and answer these questions. Figure 4, shows the number of comments that a post on a given day received (Mohan, 2008). At the end of the semester, the students said the marks for VC usage motivated them to use the VC. The number of students who passed the final examination increased from 40% to 67%.

2ND VIRTUAL CLASSROOM

The 2nd VC provided the 100 students with a choice, to choose to use the VC or not to use the VC. The students who choose not to use the VC, they were given all the instructor's questions posted and had to write their answers and submit in order to

be evaluated for the 10%. All the students were Mechanical, Chemical or Petroleum engineering students and was taught by the same instructor at the same time in the auditorium. An examination was given before using the VC to get an idea of mathematical background which was used for the initial questions posted. The VC option was chosen by 80 students while 20 students chose no VC. The idea of giving choice was to let the student take ownership of his/her own learning. This experiment aimed at investigating whether the needs of students with respect to technology as a scaffolding tool, can aid students' performance. The VC users benefited by collaboration and learning at own pace. A student can choose to read the questions and comments, correct an incorrect comment, answer a posted question or ask a question. The anonymous student was motivated to learn at his/her pace and constructed new knowledge without the judgment of peers.

This trust in ownership and autonomy in learning is highly advocated by constructivist theorist

Figure 4. Graph showing usage

Jean Piaget “who articulated mechanisms by which knowledge is internalized by learners. He suggested that through processes of accommodation and assimilation, individuals construct new knowledge from their experiences.” According to Piaget, assimilation is when individuals incorporate new experiences into an already existing framework without changing that framework which can be faulty if their understanding is not clear. Whereas, accommodation “is the process of reframing one’s mental representation of the external world to fit new experiences. Accommodation can be understood as the mechanism by which failure leads to learning: when we act on the expectation that the world operates in one way and it violates our expectations, we often fail, but by accommodating this new experience and reframing our model of the way the world works, we learn from the experience of failure, or others’ failure.” This was further cemented by students being able to submit questions in their VC which promoted creative, critical and problem solving skills in the cognitive domain. While in the affective domain they developed social competencies like respect, appreciation and caring about the views of their classmates. This, in today’s society is an important

ingredient in companies with respect to teamwork and being a team player.

The VC served as a flexible, accessible and convenient community providing the ingredients necessary for collaboration. Figure 5 shows an example of a dialog from 2 VC users, Sparkle and marz. Sparkle commented and marz commented on Sparkle’s comment. This demonstrated marz reflected on sparkle’s comment and new knowledge evolved hence marz commented on sparkle’s comment (Mohan, 2011).

“The learning community was like an extended family and the friends that I made here became the most important reason for me to come to class and to continue with my college education”

Figure 5. Dialog among students

sparkle said...

$5\cos x + 4x^5 + 8$
integrated form is $5 \sin x + \frac{4}{6} x^6 + 8x + c$

marz said...

SPARKLE CAN I ASK WHY U INTEGRATED
THE 8 isn't that a constant
THIS IS HOW I WUD HAVE INTEGRATED IT.
add 1 to the power
 $4x^6 + 5 \sin x + c$
because c is the constant

Figure 6. Graph comparing performance virtual classroom vs. no virtual classroom

(Hesse and Mason, 2003). Learning communities create learning environments where students are not expected to be passive listeners, taking notes and memorizing facts, but instead are expected to work together, reading, writing, talking, and relating their learning to their daily lives.

Figure 6 shows the comparison of the % of each grade. It can be seen that 0% of the students got A+ in the no-VC approach while 12% of the students got A+. The % of failure must be also noted. The results suggests the VC does cause an increase in performance and also a deeper understanding displayed by three times the A's were achieved with a lot of A+s. The results obtained from the students who chose no VC had a pass rate increase from 40% to 48% while the students who chose VC had a pass rate increase from 40% to 69%.

3RD VIRTUAL CLASSROOM

The 3rd VC focused on removing the traditional classroom for teaching. This approach was based on the university of Wisconsin-Milwaukee (Garnham & Kaleta, 2002) suggestion that students learn more in blended courses than they do in comparable traditional class sections. Blended course instruction offers more choices for content delivery and can be more effective than courses that are either fully online or fully classroom-based (Singh, 2003). A group of 28 repeaters (students who failed the course) could not attend the scheduled 5:00 pm – 9:00 pm repeaters class due to transportation problem. A physical classroom was available once a week for a lunchtime

period only and this was used for either official assessments or tutorials. The instructor used the knowledge gained by reading comments from the previous VC to address foundational problems with these students. Once these foundational problems were cleared, focus was more on the identifying the learning style of the student.

Figure 7 shows the result of the repeating students. The normal pass rate at UTT for 1st year Mathematics was 40% and the result reflects an increase in pass rate to 82%.

4TH VIRTUAL CLASSROOM

The 4th VC demonstrated students evolving when they decided they wanted to build the VC. They selected a social media, Socialgo, to build the VC. The students also included posting of videos and pictures in the VC. The students asked to also act as an instructor in posting reflecting and thinking questions. The identities of these students remained anonymous. Figure 8 shows the positive

Figure 7. Graph showing performance using blended approach

Figure 8. Graph showing performance using social virtual classroom

results in terms of improved performance. The average pass rate of the 4 disciplines showed an increase in pass rate from 40% to 62% with 2 individual disciplines above 80% pass rate.

Table 1 (Mohan, 2010) show a summary of the results from the 4th VC. Even though the non-academic parts, videos and pictures comments were both more than 100 while the academic part, blogs comments was 87, the blog postings have an average of more than 31 comments to each posting. This demonstrates that the postings stimulate thoughts from other students. The results suggest that the non-academic postings stimulated interest which lapped over to the academic posting. The students' academic postings were more than 25% of the postings.

Mohan (2013) demonstrates that when a student has ownership of his/her learning and is motivated, he/she can be very creative. For example Tom registered himself as Dr. MathsBsc-MscPhd, who depicted a brilliant student but Tom

also registered himself as Big Bird, who was an extremely weak student. In a similar manner, the instructor was registered as the instructor, using the instructor's name, and was also registered as a weak student, Black Eye-Peas. Several guidelines were followed in the VC. These guidelines and the motivation for each one are given in Table 2 (Mohan, 2013).

Another important aspect of the VC was that many topics were available at the same time. A student can move at his/her individual pace of learning without interfering with another. This was especially important since time flexibility in learning a topic was essential. In Figure 9, the graph shows a summary of a portion of the 2020 comments, grouped by the time posted, timestamp (Mohan, 2011). A VC must be time convenient as shown in Figure 8.

Figure 9. Graph showing usage at certain times

Table 1. Comments generated for the different type of items

Forum	17	47
Pictures	106	12
Blogs	87	2069
Videos	105	231

Table 2. Guidelines for the social virtual classroom

Guideline	Rationale
Allow students to register as anonymous users	This guideline which ensures that all registered users are anonymous is intended for students who may have a social, cultural, or academic difference which may contribute to low esteem of themselves. It also caters for students who have a barrier due to peer pressure or other circumstance. This was used to establish collaboration.
Post stimulating fundamental questions	In order to help students extract their knowledge and realise what they know and hence what they do not know, the questions posted by the instructor were not about solving questions but rather stimulating, thinking and opinionated questions. This approach was also intended to encourage collaboration among students.
Establish that every comment is valuable	A student's comment which is participation was encouraged. The accuracy of that comment was not considered. This approach was used in an attempt to relate to all students' different backgrounds.
Motivate rebuilding of comments by collaboration	This guideline emphasised collaboration since strength can be obtained by variety. When a student freely shares his/her knowledge and other students contribute by making comments to that knowledge, the student can reflect on those comments which may then give him/her the opportunity to re-create their knowledge.
Provide quick feedback	The guideline of quick feedback was aimed at encouraging students that other students are important and need to be heard so that they could expect a quick response. In most cases, a comment would be answered within 2 days by either a student or an instructor.
Ensure 24/7 and absolutely free	An important consideration in this experiment was to ensure the approach was convenient and affordable. This approach must be adaptable to each student's constraints in terms of time, place and cost. An internet-based application has the features of 24/7, anytime and anywhere. <i>SocialGo</i> is a free social networking application.
Attract student interest by posting a video on the social community	A student can feel a sense of satisfaction if they are the first to post a video for other students to see. This guideline is intended to help those students who are weaker academically so that they can still participate in building the social community. The feeling of belonging and creating may have positive influences on a student.
Engage students through interesting non-work postings	Since these digital native students are so visual, relating to a video or social aspect is always appealing. If the student can be engaged with the videos then the student may have a spill over and may also engage with the subject matter.
Encourage students to provide feedback to one another	The students were provided the opportunity to comment on one another's comments thereby enabling the typical teacher-student role to be shifted since now the student can take up the role as the teacher. This approach is two-fold. The first is the virtual classroom requires a lot of time from the instructor, if only for the instructor to correct or make suggestions to comments. The confidence of a student being able to teach or identify weaknesses in the knowledge of others may boost a student's self esteem. The second is the students getting feedback.
Enforce that comments can be questions, answers, suggestions or illustrations	The guideline assumes that a student's knowledge is varied hence collaboration by answering or illustrating in the manner that is unique to that student can be beneficial. Any type of comment, questions, answers, suggestions or illustrations were all considered equally valuable. The idea is that the students can build on each other's knowledge
Reward students based on the quantity of comments, not on the quality	The guideline of rewarding students (by awarding marks based on usage) is based on rewards which are given when students are playing computer games. The reward is really to motivate the student to keep trying and the more the student tries, the more points (marks) will be obtained.

This VC demonstrated that the student can posted thinking questions that led into discussions at interesting times such as 2:00 am. The student feedback was prompt and many users were correcting or improving comments. At the end of the experiment, the students were asked to fill out a survey. Each question had four responses strongly agree, agree, disagree and strongly disagree. The

survey was divided into two categories using the VC and the community. Some of the questions from each of these two categories are shown in the Table 3 below. The names of the students were not collected in the survey.

From Table 3 (Mohan, 2013), it can be seen that 80% of the students strongly agreed that being anonymous was important to them, suggesting

Table 3. Student feedback

Using the Social Virtual Classroom	Strongly Agree	Agree	Disagree	Strongly Disagree
Were you encouraged to think outside the classroom by using the social virtual classroom?	40	38	22	0
Did reading other users' comments help you in your understanding?	59	30	11	0
Was being anonymous important to you?	80	17	3	0
Did the social virtual classroom help you to build more confidence in your work?	45	23	32	0
Would you prefer more courses to use this approach in teaching?	69	31	0	0
The Inclusion of the Social Community				
Did you believe that the social aspects of the social virtual classroom were helpful?	65	17	18	0
Was looking at other users' videos interesting to you?	44	30	21	5

that the anonymous feature was a very important feature. 59% of the students stated that reading other users' comments helped in understanding the subject matter. Another interesting result was that 69% of the students preferred more courses to use the VC approach in teaching. On the negative side, 32% of the students did not agree that the VC helped build more confidence and 22% of the students said that they were not encouraged to think outside the classroom by using the VC.

FUTURE RESEARCH DIRECTIONS

These experiments reflected that VCs led to an increase in the pass rate of 1st year Mathematics at the University of Trinidad & Tobago. Four VC were used. The 1st VC, all students had to use and the pass rate was 67%. The 2nd VC, students were given choice and the pass rate was 69%. Future research direction is to investigate whether there is any relationship between the frequency of the VC usage and the grade obtained. Another future research would be to investigate whether anonymity is a key factor in the VC. The VC should be instructor independent hence future research should confirm this by repeating the experiment but change the traditional classroom instructor.

The 2nd VC offered choice of with or without technology and the pass rate was increased by 29% as compared to 8% respectively. A VC with technology was more than three times successful as without technology. That result is quite significant therefore further research must be to repeat this experiment to confirm technology does indeed have a positive impact in teaching.

The 3rd VC was for repeating students with the constraint of no traditional classroom. Future research directions is to confirm the result is accurate by repeating a number of times. This can lead to an interesting option for teaching repeating students.

The 4th VC incorporated non-academic postings eg videos and pictures. Future research direction can be to investigate if culture and social postings can contribute in further enhancing the pass rate.

CONCLUSION

The experiments described in this chapter suggest that VCs do cause an increase in the pass rate of mathematics. The VCs was designed to stimulate students to think by posting stimulated opinionated questions. In the 2nd VC that the students who

chose no VC were given the same stimulated opinionated questions on paper which resulted in an increase from 40% to 48%. The 1st and 2nd VCs got a greater increase of 67% and 69% respectively suggesting that technology assisted students with their cognitive skills. This was possible with an environment fostering students' collaboration may motivate students to analyse and evaluate their existing knowledge. Thus enabling each student to build on their individual knowledge demonstrating self-centred learning. The success of the experiment was based on improved pass rate which was accomplished by the 4 VCs but the most impressive VC was the one 3rd VC which increased to 82%. This was the smallest group with 28 students and this was also repeating students. Another observation from the experiments was the students indicated that they were more inclined to use the VC since they were anonymous to other students. The prompt feedback encouraged the students to use the VC more frequently thus allowing them to evaluate and analyse their knowledge meta-cognitively.

KEY TERMS AND DEFINITIONS

Anonymous: Anonymous meant identity was unknown thus a student was free to share his/her understanding. It also provided a mystery within the VC. Many students registered as different user in order to get more usage. Thus developing an opportunity for a student to be creative.

Autonomy: The student is given many opportunity to make decisions thus taking control of his/her own learning. The student decides if to share his/her understanding or if to reflect and then comment on another student's comment or if to disguise as two different users.

Collaboration: Collaboration in the VC is building team spirit. It is an opportunity for students to come together and share their understandings and help build one another so that everyone has the same understanding which will lead them to pass mathematics.

Virtual Classroom Usage: Encouraging students to share his/her understanding so if that understanding was incorrect, it can be reconstructed and become correct. The usage is how many comments were made so the more comments the more a reward.

Virtual Classroom: The VC was an online environment where students came together for learning and/or teaching. This environment facilitated individual personal needs like convenience in time and location, motivating students to share understanding by making comments and engaging students in dialog and feedback and most important providing an opportunity for students to fix his/her background knowledge.

Integrated Paper-Based and Digital Learning Material for Smart Learners

E

Sabrina Leone

Università Politecnica delle Marche, Italy

SMART LEARNING, SMART LEARNERS, AND INCLUSIVE LEARNING

Smart learners are lifelong learners (Leone, 2010) whose potential is unleashed by the seamless use of smart technologies (i.e., smartphones, tablets, tablet PCs, sensor network nodes, contact-less smart cards, RFID and QR codes) to access huge amounts of open resources and connections, anywhere anytime. Personal, and personalised, smart technologies increase a learner's independence in a novel way, and makes the context for engaging in study more tailored and potentially self-directed (Middleton, 2015).

Smart learning encompasses any teaching and learning approach that flawlessly accommodates technology and enhances practice through social uses of new inclusive spaces. Fruitful interactions are the core of a smart learning cycle and are supported by a smart learning environment (Liu, Huang & Chang, 2015). Indeed, the current digital learning environment is gradually evolving into the smart learning environment (Li, Chang, Kravcik, Popescu, Huang, Kinshuk & Chen, 2015), that is a user-friendly space that facilitates easily accessible, appealing and effective learning. A learning environment may be considered smart when it includes adaptive technologies or innovative features and capabilities that improve understanding and performance. Specifically, features of smartness are

1. Conversational support for learners, teachers and designers,

2. Dynamic updating of student profiles, resources and databases, and
3. Automatic [re-]configuration of interfaces to adjust to different learners and learning situations (Spector, 2014).

The concept of smart learning includes that of ubiquitous learning (uLearning). The only difference stands in the higher power of next generation (smart) technologies that are creating disruptive learning landscapes and learners' profiles.

Today's students expect always-on, available-anywhere information and personalised, multichannel learning. The term "classroom" is becoming more figurative than literal (IBM, 2015). In a smart learning environment the physical and virtual dimensions merge (Liu, Huang & Chang, 2015), and learning is inclusive.

Inclusive education is an essential component of lifelong learning; it is concerned with an individual's effective participation in society and with the achievement of his/her full potential. The affordances of new educational technologies can enable the development of uLearning environments and of multimodal learning contents that foster inclusion, personalisation and interaction, provided that a learner-centred and technology-enhanced approach is adopted.

Internationally, inclusive education is increasingly understood more broadly as a change, in a holistic approach, that supports and welcomes diversity (in race, economic status, social class, ethnicity, language, religion, gender, sexual orientation and ability) amongst all learners (UNESCO, 2009).

Since learning takes place in many contexts, formal, non-formal and informal, inclusive and quality education become synonyms and are vital for the development of more inclusive societies.

Specifically, quality learning is characterised by two important components: the learner's cognitive development, and the promotion of values and attitudes of active citizenship and/or of creative and emotional development.

An inclusive curriculum is based on the four pillars of education for the 21st century – learning to know, to do, to be and to live together (Delors et al., 1996). Promoting inclusion means stimulating discussion, encouraging positive attitudes and improving educational and social frameworks. This involves changes in content, approaches, structures and strategies in order to provide all learners with flexible and personalised learning to meet individual needs, abilities and learning styles.

uLearning, supported by the growing diffusion of wireless smart technologies and institutional policies, is becoming more and more a modality of flexible and participatory learning to be adopted in and out of the classroom exploiting smartphones, tablets, tablet PCs, sensor network nodes, contactless smart cards, RFID (El-Bishouty, Ogata, & Yano, 2007) and QR codes.

Thanks to this technological growth, a personal learning environment could be embedded in everyday life (Ogata & Yano, 2004) and become a Computer Supported Ubiquitous Learning (CSUL) environment, characterised by permanency, accessibility, immediacy, interactivity, situatedness and adaptability (Curtis, Luchini, Bobrowsky, Quintana, & Soloway, 2002; Leone & Leo, 2011a). Learning theories for CSUL are authentic learning (Brown, Collins & Duguid, 1989), situated learning (Lave, & Wenger, 1991) and learning by doing (Schank, 1995).

It is widely acknowledged that information and communication technologies (ICT) enrich the learning experience (UNESCO, 2012). Anyhow, the focus has to be placed on learning, rather than

on technology in itself. In a technology-enhanced learning approach, the advantages arising from the integration of ICT in the learning curriculum have to be assessed within the learning experience, the usefulness of learning and its enhancements (Leone, 2008; Leone & Leo, 2011a).

Pedagogical and psychological researchers have debated for decades on a common understanding of “effective learning”. According to recent literature (Bulu & Yildirim, 2008; Calvani, 2006; Ellis, 1999; Liu, Huang & Chang, 2015; Wasson, 2007), social interaction among learners is a major element of the learning process, indeed, it can decisively impact on learning outcomes (Agostinho, Lefoe, & Hedberg, 1997).

Cooperation is an essential factor in the construction of an “effective learning” environment since it engages students in knowledge construction through interaction and negotiation with their peers. Cooperation enables learners to discuss, argue, agree and reflect on ideas, principles and knowledge. In the design of a suitable –situated, real – learning environment prior attention has to be paid to knowledge construction and effective learning, that is to learning relevant for learners (Johnson & Johnson, 1994).

Smart learning emphasises technology-embedded learning to enhance cooperation and interaction between learners (Bae, Shin, Kim & Choi, 2015).

This work aims to illustrate the *QRcode* format, a framework that supports uLearning by the integration of paper-based and digital learning material through Quick Response (QR) code. The format was devised within the research project *Learning4All* (2009-2012) and was validated by several learning experiences of English as a foreign language (EFL) for different clusters (Leone, 2014). Subsequently, the format was selected as element of techno-pedagogical innovation in the *Eureka* project (2012-2014), a network of 11 schools in Apulia, Italy, for the enhancement of curriculum continuity from middle into high school.

INTEGRATED PAPER-BASED AND DIGITAL LEARNING MATERIAL: LITERATURE REVIEW

Paper and traditional books have been used as basic tools in developing knowledge-intensive tasks and learning (Chao & Chen, 2009). However, a paper textbook can be combined with ubiquitous technologies in a whole to deepen reading comprehension and to enrich it with audio, video and grammar, vocabulary and cultural/technical/professional in-depth contents.

Paper-based learning material has been successfully enhanced by multimedia contents in experiences on annotation conducted through digital pen (Chao & Chen, 2009; Lai, W.-C., Chao & Chen, 2007). More recently, practitioners and researchers have shown growing interest for the potential of QR code as ubiquitous learners' tool, and several learning experiences have been conducted in different contexts: outdoor education (Lai, Chang, Wen-Shiane, Fan & Wu, 2013; Law & So, 2010) and outdoor students' assessment specifically (Conejo, Perez de la Cruz, Barros, Galvez & Garcia-Viñas, 2013); integrated paper-based and digital learning materials to enhance listening comprehension in foreign language learning (Law & So, 2010), to enhance reading comprehension (Chen, Chia-En Teng, & Lee, 2010;), to provide support in maths homework (McCabe & Tedesco, 2012), to convey directions to English language learners and recordings for students who have difficulty in reading (Shumack, Lewis, Simmons & Carpenter, 2013), and to encourage students' interaction during face-to-face lectures (Law, 2013). Most common uses include access to web sites with course information and study materials (Bobeva & Hopkins, 2012). Nevertheless, little literature (Leone & Leo, 2011a; Leone & Leo, 2011b; Leone, 2012; Leone, 2014) is available about the principles of instructed learning in the use of paper-based learning material integrated with digital material through QR code within a definite learning format or model.

Thanks to its two dimensions (vertical and horizontal), the QR code can store greater amounts of information and services (i.e., website addresses, text, contact details) (Ramsden, 2009; Savarani & Clayton, 2009) that learners can readily, anywhere and anytime, decode by a mobile device with an embedded camera and code reading software installed. Besides fostering flexibility of provision, the integration of QR codes with paper-based learning material also offers personalisation of learning because different learning styles and approaches to the use of ICT for learning can be accommodated.

THE QR CODE FORMAT

QRcode is a technology-enhanced learning format that was devised within the research project *Learning4All* (2009-2012). The project investigated on how an aware adoption of ICT can contribute to improve the quality of teaching, in particular for students with special needs (UNESCO, 2009). *Learning4All* included seven research units: Politecnico di Milano - coordinator -, IMATI CNR di Genova and the Università di Bari, di Bologna, di Perugia, del Salento and Politecnica delle Marche (UNIVPM).

The *QRcode* format consists in the integration of paper-based and digital learning material through QR code, aimed at facilitating personalised and flexible (anytime, anywhere) learning. Multimedia contents are coded by the teacher in QR code and are then easily accessible by a decoding software which is supplied with many mobile devices or is downloadable free (Leone & Leo, 2011b). The *QRcode* format is potentially adaptable to all disciplines and was implemented in several learning experiences of EFL for different clusters, with good results: in February-June 2010 in three different scenarios (adult lifelong learners, in-service teachers and secondary school students) (Leone & Leo, 2011a), in February-March 2011 with 4 classes of a secondary school and in March-

April 2012 with 2 classes of a secondary school for surveyors (in an interdisciplinary module EFL – Building Construction) (Leone, 2014). Further, as element of techno-pedagogical innovation in the *Eureka* project (2012-2014), the format was implemented in the following sessions: in October-November 2012, initial training of 80 in-service teachers from the many partner institutes; in April-May 2013 and in January-February 2014, 2 interdisciplinary paths with 8 3rd-year classes of a middle school together with 8 1st-year classes of high school.

Needs, Objectives, and Competences

General learning objectives of the *QRcode* format are: learning to learn, promoting the deepening of contents in different contexts and by different means, favour interdisciplinarity of knowledge domains, favour continuity between in-class and out-of-class activity (integration between formal and informal learning). Specific learning objectives are to: facilitate the acquisition of basic, communicative and multimedia, and digital competences; favour a better general/specific comprehension of one or more of the topics developed; support motivation, participation and interest for a discipline; promote cooperative and collaborative learning. The *QRcode* format can develop basic and higher cognitive and social competences (knowing and understanding the topic treated, communicating adequately in relation to the context, retrieve information from various sources and re-elaborate it in a personal way, meet a new culture in a view of cultural pluralisme), crosscurricular (autonomous study and in-depth analysis, problem solving, relational skills), of citizenship and digital (understanding the affordances of ICT for knowledge sharing and collaborative construction) skills.

Learning Strategies

The *QRcode* format can be developed through exercises, brainstorming (encoding in QR code

of forums and wikis), collaborative and cooperative learning, learning by doing, problem solving, webquest, game based learning, simulations in immersive virtual environments. The format can be an effective inclusive learning tool since it facilitates personalised and flexible learning if a learner-centred approach is adopted, an approach attentive to each learner's diverse needs (UNESCO, 2009). A metacognitive work that allows to enhance autonomy and responsibility could be a first step towards inclusion.

Organisation

The physical places to implement the *QRcode* format are the classroom with a wireless connection or a hot spot, where learners operate, individually or in a group, on paper-based and digital learning material, by the various mobile devices available, and any other place by mobile devices with an Internet connection. The learning environment is, therefore, both physical (classroom and class) and virtual (web-based, with interactive activities, and/or 3D) according to what the teacher adopts. The length of the implementation can vary in relation to the number and the extension of the uLearning modules of the designed curricular path. Necessary human resources are the teacher, that defines strategies, objectives, contents and activities, and the ICT technician, that installs/checks the QR code decoder software in the mobile devices in use, checks the Internet connection and deals with troubleshooting.

Evaluation and Assessment

The *QRcode* format is monitored at the beginning and at the end of its implementation, in order to evaluate its effectiveness and rating from the participants' point of view (evaluation), and in terms of achievement of learning objectives (assessment). For the evaluation, the data are collected (1) by entry and exit anonymous surveys, to record students' digital skills, motivation and expectations on the format (entry survey), and students' feedback (exit survey); (2) by interviews, to record

teachers' motivations for the choice of the format, expectations and context of implementation (entry interviews) and teachers' achieved results and impressions (exit interviews). Assessment is carried out by close, semi-structured and/or open tests, and it consists in an entry test (prior knowledge and competences), formative tests (at the end of each learning unit) and a summative test (at the end of the learning path).

Recommendations for the Optimal Implementation of the Format

The *QRcode* format is a very flexible tool. Nevertheless, thorough organisation and management of hardware and software are success key factors of the experience. Moreover, relevant elements are: a learner-centred and technology-enhanced approach, drawn on constructivism (Jonassen & Land, 2000); an adequate familiarisation of the students with learning tools and environments; check of the accessibility of the necessary devices; modulation of space/time of class and autonomous work; collaboration with other teacher to create an interdisciplinary path; engagement of the educational institution as a whole as stakeholder of techno-pedagogical innovation.

SWOT Analysis

Strengths of the *QRcode* format are the provision of personalised and flexible learning. Weaknesses are initial technological difficulties that can cause demotivation and disengagement. Opportunities are many: opening to a wide range of learning paper-based and digital materials; use of open software and learning materials; possible effective integration of the format in the curriculum; possible spur for interdisciplinary activities. Vice-versa, possible threats are a teacher-centred approach, that risks to void the flexibility of the format, and the limits of the participants' mobile devices (speed of the processors, small displays, Internet connection costs), even though the technological standard of next generation (smart) devices is high.

CHARACTERISTICS AND OUTCOMES OF THE RESEARCH EXPERIENCES WITH THE FORMAT

All the experiences of implementation of the *QRcode* format have been conducted in Italy for:

1. Nine different clusters of learners of EFL:
 - a. In February-June 2010 in a refresher course for secondary school teachers (23 participants, 10 weekly 3-hour lectures), a language certification course for Italian secondary school students (upper classes, 16 participants, 17 3-hour lectures twice a week) and a course for Italian adult beginners (15 participants, 20 weekly 3-hour lectures). Participants were 54 in all. The author was teacher-facilitator and tutor of the research experience at the same time;
 - b. In February-March 2011 (4 weeks, 9 hours in all for each class) with 4 classes (second- and forth-year students) of a secondary school, 85 learners in all. The author was tutor of the research experience, in support of the two curricular teachers;
 - c. In March-April 2012, on the basis of the preceding research experiences, an implementation enriched with cooperative work, on an interdisciplinary module EFL-Building Construction (4 weeks, 3 hours a week for each class) with 2 upper classes of a secondary school for surveyors, 45 learners in all. The author was the coordinator of the research experience and English teacher, at the same time;
2. Three clusters of learners in interdisciplinary paths within the *Eureka* project (2012-2014) (the author was the coordinator of the techno-pedagogical innovation of the project, one of the teachers' trainers and tutor in the last two experiences):

- a. In October-November 2012 in the initial training of 80 in-service teachers from the many partner institutes (2 in-presence 4-hour workshops and the ongoing distributed community of practice *Comunità di Pratica Progetto Eureka*, in the eLearning space www.elearnigplace.it/corsi);
- b. In April-May 2013 (4 weeks, 9 hours a week for each class) an interdisciplinary path on Italian, music, history, geography, French and maths with 4 3rd-year classes of a middle school together with 4 1st-year classes of high school, 193 learners in all;
- c. In January-February 2014 (4 weeks, 9 hours a week for each class) an interdisciplinary path on citizenship education, geography, Italian, the arts and music with 4 3rd-year classes of a middle school together with 4 1st-year classes of high school, 187 learners in all.

In all the implementations the participants used their own mobile devices; in addition laptops were available at schools. All the courses were developed in uLearning on curricular in-presence and distance learning modules. Personalisation was realised by a great variety of graded learning materials (on the basis of the entry assessment

test and evaluation survey, and proposed in hard copy and pdf file, both integrated with in-depth digital contents in QR code), web-based interactive activities and self-assessment.

In the interdisciplinary implementation EFL-Building Construction of March-April 2012 (Leone, 2012) the teaching team defined strategies, objectives, contents and activities, and enriched the experience with cooperative learning, either in presence and in eLearning (*PlaLE – Personal language Learning Environment*, in <http://www.elearningplace.it/corsi/course/category.php?id=14>), with which learners had already familiarised in EFL since the beginning of the school year.

Specifically, objectives of the implementation of the *QRcode* format in all cooperative and interdisciplinary implementations were metacognition, the synergic enhancement of disciplinary, technical-professional (when applicable) and language (when applicable) skills, the acknowledgement of the importance of cooperative learning in the participants' personal growth, the acquisition of new learning tools for cooperative work, the activation of students' participation in group work, the enhancement of peer-scaffolding.

Contents included domain knowledge, micro-language (if applicable), communicative functions (for foreign languages), inherent grammar and vocabulary, and cultural in-depth topics.

Figure 1. Integrated activities in “Talking about the past”

Week 1/class 2: Wednesday 9th (5B) and Thursday 10th (5A) February
Expressing a sequence of events - past tenses revision (I)

Activity 1 - An apartment in London.
 Read the following text and turn it into the past.

This apartment is in the heart of Chelsea, one of the most fashionable areas of London. It has two beautifully furnished bedrooms and a fully fitted kitchen. It is not far from Buckingham Palace, the Royal Albert Hall, Knightsbridge, Sloan Square and the Natural History and Victoria and Albert Museums. The nearest underground stations are South Kensington and Sloan Square. The minimum stay is seven nights. There is a direct dial telephone and satellite tv. A maid service is guaranteed five days a week. You can also have a wireless broadband Internet connection. There is also off-street parking for residents.

Activity 2
 unit 9 - 10: ex. 3 - the simple past
 of regular verbs + ex. 5 - the
 simple past of irregular verbs

Figure 2. Content of Activity 2 (ex. 3), in QR code in Figure 1

Module B
Units 9-10

GRAMMAR
3. The Simple Past tense of regular verbs
Write down the sentences using the prompts given. Remember to use the Simple Past. Then click on OK.

1. Greetings and reply
2. The past tense of 'to be'
3. The Simple Past tense of regular verbs
4. Questions with 'How'
5. The Simple Past tense of irregular verbs
6. Similarity
7. Don't speak too fast!
8. Let's talk about holidays
9. My first novel

Practice **Test**

Module B > Units 9-10 > 3. The Simple Past tense of regular verbs

Margaret Layton, Marina Spiazzi, Marina Tavella - Slides ZANICHELLI

You / to order / a pizza for dinner / last night?	
What subject / Mark / to study / yesterday afternoon?	
We / to wait / for them in front of the cinema / last night.	
Miranda / to watch / a beautiful film on TV / yesterday.	
David / to live / in New York / last year?	
You / not to lock / the door / this morning.	
Bob / not to invite / Polly / to his birthday party.	
Liz / to look / very tired / last Sunday.	

Glossary | Grammar | Print | Exit

Figures 1 and 2 show an extract of the activities proposed in EFL for the communicative function “Talking about the past” and for those codified in *QR code*, respectively.

In all the 9 experiences in EFL, learners carried out an extensive range of tasks in relation to the four language skills (see details in Leone & Leo, 2011a; Leone, 2012; Leone, 2014).

As a whole, results of all the experiences emphasise that learners’ motivation and active participation grew as their awareness, self-confidence and familiarisation with the learning environment improved. In the exit interviews the teachers, too, expressed full satisfaction with the students’ participation and learning results (even learners who were usually demotivated progressed in terms of cognitive, digital and crosscurricular skills), and with their personal and professional empowerment.

The main difficulties were technical-organisational ones and in a few occasions due to the teacher’s mismatching approach; in particular:

- Teenagers showed to be false digital natives; as a result, even though an extensive phase of familiarisation preceded the start of the experience, during the first and second week 40% and 10% of the time available respectively was forcedly dedicated troubleshooting on the mobile devices;
- Because of a recurrent insufficient Internet connection in some of the classrooms used, it was necessary to move the learners in alternative locations;
- In some sessions a lack of the already configured devices occurred (participants simply forgot to bring them);
- In some sessions learners were rather passive and disoriented because of discontinuity in the learning path (decontextualised activities) and insufficient teacher’s facilitation (guide, scaffolding and feedback during the tasks);
- Insufficient engagement and interest for the experience within the teachers’ institutes.

The results obtained from the implementation of the *QRcode* format in the different scenarios show an important positive impact on different aspects: the uLearners' disciplinary skills, management of ICT tools, satisfaction levels with the flexibility and personalisation of learning, as well as on the contents proposed and cross-curriculum objectives such as developing autonomy, building learning confidence, empowerment, a positive attitude and motivation towards a new way of learning, results which come to support the effectiveness of the model implemented (Leone & Leo, 2011a; Leone, 2012).

FUTURE RESEARCH DIRECTIONS

In the next future, the *QRcode* format could be extensively used in different grades of instruction and in teachers' continuous professional training. In addition, a pilot implementation of the format with augmented reality is starting. In order to fully exploit the potential of the format, scaffolding might be provided as an added service to tackle large margins of improvement that have emerged in the participants' digital skills, in their approach to teaching and learning, in their approach to the adoption of ICT in the curriculum as a chance of holistic change and growth towards smart inclusive education.

CONCLUSION

Personal, and personalised, smart technologies increase lifelong learners independence in a novel way, makes the context for engaging in study disruptive, more tailored and potentially self-directed, and allow for access to huge amounts of open resources and connections, anywhere anytime.

The affordances of smart technologies can enable the development of uLearning environ-

ments and of multimodal learning contents that foster inclusion, personalisation and interaction, provided that a learner-centred and technology-enhanced approach is adopted.

The *QRcode* format has been devised with the aim of providing personalisation and empowerment to ubiquitous lifelong learners facilitating the acquisition of some of the skills necessary for the 21st century.

The format is very flexible for both the teacher-facilitator and the learners, and can be enriched with interdisciplinary and cooperative learning experiences.

The outcomes of all the research experiences carried out to date highlight an important positive impact on the participants' disciplinary competences, acquisition of skills in the use of new digital tools, satisfaction for flexibility and personalisation of learning and for the contents and the crosscurricular competences, and validate the potential of the implemented framework. However, success keys of the experience are: (1) punctual organisation and management of the necessary hardware and software; (2) a suitable students' familiarisation with the learning environment (technology, tools and learning approach); (3) a learner-centred approach; (4) a technology-enhanced, rather than technology-driven, approach.

KEY TERMS AND DEFINITIONS

CSUL (Computer Supported Ubiquitous Learning) Environment: Everyday ubiquitous learning informed by the theories of authentic learning (Brown, Collins & Duguid, 1989), situated learning (Lave, & Wenger, 1991) and learning by doing (Schank, 1995).

Formal Learning: Hierarchically structured, chronologically graded educational system running from primary through to tertiary institutions.

Inclusive Learning: Learning that allows to meet not only special needs, but also diverse needs (e.g., different learning styles).

Informal Learning: Unstructured learning that allows persons to acquire attitudes, values, skills and knowledge from daily experience, within the individual's environment (i.e., family, friends, peer groups, etc.).

Lifelong Learning: A holistic vision of learning in different contexts (formal, non-formal and informal) and throughout life, based on the evolution of provider-driven education toward personalised learning and aiming at improving knowledge, skills and competencies within a personal, civic, social and/or employment-related outlook.

QR (Quick Response) Code: A bidimensional code (it displays information in both vertical and horizontal directions) that can hold larger amounts and different kinds of contents (e.g., website addresses, texts, numerical information, contact details) than a normal bar code (monodimensional). The information stored in a QR code can be readily decoded and accessed by a mobile device with an embedded camera and free code reading software installed.

QRcode Format: A technology-enhanced learning format to be implemented in a learner-centred learning environment to offer inclusive, personalised (different learning styles and goals) and flexible (anytime, anywhere) learning by the integration of paper-based and digital learning materials through QR code.

Ubiquitous Learning: Wireless learning supported by a large number of cooperative small nodes with computing and/or communication capabilities (e.g., handheld devices, sensor network

nodes, contact-less smart cards, RFID and QR codes) and characterised by high mobility and embeddedness.

University College Cork, Ireland

INTRODUCTION

The use of social media technologies to connect with peers/colleagues is prevalent amongst students and practitioners alike. These technologies are being used to share ideas, content, resources, and experiences for both social and professional purposes. However, modern learning environments do not always implement the latest technologies and are therefore failing to support the needs and career expectations of Generation 2020. Thus, technology enhanced learning is proving invaluable in creating interactive collaborative learning environments that can address the needs of future graduates. The social business gaming platform considered in this chapter leverages the social networking concept in an academic environment. This study was undertaken in order to develop Information Systems (IS) security skillsets through the creation and facilitation of social business gaming. The online business game required students to apply what they have learned to problem situations to further develop their understanding of IS security (ISS) topics. The problems posed required learners to prove their understanding of the material being taught in the traditional lecture, and then apply what they had learned in an online environment, allowing students to both collaborate and compete against their peers in a

series of challenges. The game was utilised as a part of the continual assessment process to evaluate group interaction, role-playing, competition and learning in an ISS assignment and facilitate the students to measure their own performances of understanding. Thus, the game was not just an assessment mechanism for grades, but also a learning tool. This chapter focuses on a group of final year undergraduate students completing Bachelor of Science in IS and outlines the online ISS environment used in the study.

BACKGROUND

Organisations actively use simulated environments to both test (e.g. psychometric) and train (e.g. virtual trading of stocks and case study analysis) employees. Medical and scientific educators actively promote the learning of these disciplines through simulation and modeling tools (Quellmalz & Pellegrino, 2009) but to date social gaming has not been widely applied as a learning aid for business and IS (security) graduates. This chapter endeavours to leverage social media technology to enhance and support the learning and assessment mechanisms utilised in an undergraduate final year ISS module with the objective of providing students with a practical proactive knowledge of

DOI: 10.4018/978-1-5225-2255-3.ch223

the implementation and management of ISS in business, an increasingly important and understudied topic (White et al., 2013). The chapter is structured as follows; the subsequent section considers the area of learning, focusing on the weaknesses associated with traditional learning and highlighting how learning tools may overcome many of these. Following this, the nature of ISS education is presented and the workplace of the future is considered with particular emphasis placed on the need for business graduates with skills in social media technology. The research approach is then outlined. The case is presented and discussed and finally attention is attributed to the conclusions of the study.

Traditional Approaches in Teaching and Learning

Traditional learning approaches dominate third level education, however, more recently these practices are complemented by alternative approaches to teaching and assessment. This includes the use of Web 2.0 technologies (i.e. podcasts, social network sites, media sharing platforms, etc.) as a means of active learning, to further support and engage the learner (Cao et al., 2013). Traditional learning, also known as the teacher-centered paradigm, is regarded as a learning environment that encourages passive learning (Barr & Tagg, 1995), does not develop problem-solving skills, and ignores the individual needs of the students (Hannum & Briggs, 1982). It could be argued that advances in technology, such as multimedia and virtual simulations, have left the traditional classroom trailing behind, with learners expecting more and more. Social media provides a solution to these problems by incorporating the collaborative attributes associated with Web 2.0 technologies (Schneckenberg, 2009). Instructors are redesigning learning and assessment mechanisms by leveraging the dynamic interactive capabilities that social media can provide, which ultimately helps improve the essential skills students require to become business and ISS professionals. The

widely accepted criticism of the teacher centred model is that the ‘what’ rather than the ‘how’ of the instruction is delivered (Goodlad, 1984). It is argued that problem-solving and other intellectual skills are difficult to incorporate into the traditional environment due to the very nature of the educational system. Factors such as space, the grouping of students according to grades, and the duration and size of classes all hinder the desired environment. Technology enhanced learning is not the ‘silver bullet’ solution to the problems encountered in the education system, but it can provide a necessary balance to some of the limitations experienced with the traditional approach.

Technology Enhanced Teaching and Learning

Technology enhanced learning refers to the enhancement of learning using information and communication technology (ICT), with the added benefit of helping students to develop new skills with digital tools along the way (Klemke & Specht, 2013). Technology, in this instance, plays a significant role in making learning more effective, efficient, or enjoyable (Goodyear & Retalis, 2010). In the literature it is often termed *e-learning* and it can support the educator and learner in a number of ways. For example, differing learning styles can be catered for so that educators can reach more students in a variety of ways, this subsequently enhances the number of students able to learn the course material (Sulcic & Lesjak, 2001). It is imperative when an organization or university decides to implement an e-learning initiative that they develop an effective solution that recognizes the need for good learning practices, by incorporating good design and development guidelines (Sulcic & Lesjak, 2001) – such as the learning dimensions advocated by Reeves and Reeves (1997) for interactive learning and collaboration. Active learning approaches, such as case-based learning and problem-solving, have long been advocated as ways of fostering deeper learning (Healy & Neville, 2009; Boyce

et al. 2001). Similarly, for many years, organisations have been using problem-solving scenarios such as business simulations to both test and train employees. Simulations enhance the learner's logical reasoning, numeric abilities, and spatial thinking through real problem-solving scenarios. Realising the potential of such methods, however, requires active engagement from educators and learners alike (Healy & McCutcheon, 2008). For many educators, the lack of appropriate materials, learning management, assessment techniques, and guidance are often perceived as barriers to student or employee engagement. With the 'right' underlying pedagogical approach social media technology provides educators with the technical platform to overcome these well-cited issues. Quellmalz et al. (2013, p. 1111) suggest that "engaging students in interactive assessments may provide a better estimate of their more complex inquiry practices than active or static formats" – providing third levels educators with an impetus to deliver a more complete learning experience.

Social Media Enabled Learning

Extant learning theories support the view that student learning is enhanced through opportunities to work collaboratively (Prince, 2004), and virtual learning environments actively support this form of learner collaboration (Peat, 2000). Web 2.0 has revolutionized traditional media content and the way people communicate and interact. Consequently, social media technologies have the potential to support and enhance teaching and learning in higher education (Cao & Hong, 2011; Hajli et al., 2013). In fact, social media gives learners a chance to manipulate their learning environment and to participate actively in the learning process (Hrastinski, 2009). It is through these collaborative technologies that students and knowledge workers will gain enhanced insight in the knowledge at their disposal. These tools will also enable information workers to locate and connect people with certain expertise across organizations, bringing people, systems, and data

into alignment faster to respond to challenges and take advantage of competitive opportunities. In an educational context, social media, when properly facilitated and framed can help expand the potential for learning over time by creating more student connections (Chen & Bryer, 2012). Valjtaga and Fielder (2009, p58) widely support the use of social media technology as a means of skilling students in preparation for the 'real world', "we need to construct opportunities for participants in higher educational settings to practice the advancement of self-directing intentional learning projects." However, research is needed in the area of education for the use of social media applications as online learning environments, and the learning affordances they may offer (Selwyn, 2007). Currently this area is lacking rigorous and carefully conducted research (Cao & Hong, 2011). One area of the IS undergraduate curriculum that attracts considerable attention is IS security education, as it has several practical 'real world' implications in the form of accessibility of sensitive data (Sauls & Gudigantala, 2013). Extant research highlights the importance of ISS education in terms of developing an entry level understanding of security from an IT infrastructure perspective as well as the complementary analytical skills and problem solving skills (Sauls & Gudigantala, 2013; White et al. 2013). The next section considers ISS as a topic which benefits from active learning approaches through the use of e-learning environments.

IS Security (ISS) in Undergraduate Education

In just a few decades, the use of IS has formalised information management and streamlined the administration of organisations (Galliers & Newell, 2001; Dhillon, 2006). However, in the realms of IS security, one of the fundamental problems for an organisation is to choose the right kind of environment to function in. While many organisations have engaged in identifying security issues and as a result developed appropriate ISS policies, there is a clear mismatch between policies and

what is done in practice. Therefore theories-in-use have degrees of effectiveness which are learned (Mattia & Dhillon, 2003). Espoused theory and theory-in-use are a part of the double-loop learning concept which creates a mindset that consciously seeks out security problems in order to resolve them. This results in changing the underlying governing variables, policies, and assumptions of either the individual practitioner, function or the organisation. To help address this, the literature has identified the importance of producing qualified and competent graduates to manage the security challenges facing organisations today (Sauls & Gudigantala, 2013). Hence, it is vital that IS/IT security and disaster recovery are treated as core components in business IS curriculms (Patten & Harris, 2013; White et al., 2013; Kim et.al, 2006). Considering the complexity of the subject area, it is evident that teaching the know-how and know-what of an ISS course to IS undergraduates requires a hands-on approach to adequately deal with some of the concepts and underlying principles (Ilvonen, 2013; Sauls & Gudigantala, 2013). Thus, it is necessary to go beyond the traditional learning environment where the 'knowing what' or declarative knowledge base is core to the learning experience (Quellmalz et al., 2013). This includes providing real-world experiences, using real industry situations, scenarios, and exercises, by training students from both a proactive and reactive viewpoint (Woodward et al., 2013). Exploring the 'know-how', ensures that students acquire a more complete and practical experience, better preparing them as prospective managers of tomorrow (Ilvonen, 2013).

IS Graduates of the Future

The workplace is continuously evolving and adapting to support organizational and technological change (Lee & Brand, 2005). Companies and universities will experience daunting challenges as they compete for and produce the next generation of IS talent. Generation 2020s or Generation Zs are characterized by the pervasiveness and avail-

ability of technology in every aspect of their lives (Geck, 2007). Instead of educating this generation about the Internet, the focus will be providing them with the skills to leverage the value of technology (Geck, 2007). The new workplace environment expects its knowledge workers to be proactive and show initiative, collaborate smoothly with others, take responsibility for their own professional development, and be committed to high quality performance standards. Graduates will have to use IT hardware and software intensively in a richly enabling business process environment to fulfil their roles. Indeed in 'Talent 2020' strategy, Deloitte (2012) refer to the development of their 'onboarding programs', which involve the provision of technology and resources to new employees as a means of enabling their efficient and effective engagement with the workplace. Notably, college students practice poor security behaviors and fail to properly use computer security tools (Mensch & Wilkie, 2011), thus emphasising the need for IS students to gain a critical understanding of the global issues of information security and assurance from their college education (White et al., 2013). With this in mind, 'knowing how' through active learning has become a formative part of the IS curriculum as the nature of technologies and work practices have changed. In addition, by utilizing technology in teaching and learning, it encourages student engagement and better prepares students for the work environments already embracing such technologies (Doyle et al., 2015). Subsequently, we endeavour to investigate how potential IS graduates leverage social media technology in a manner that enables them to appreciate, first-hand, the 'real world' implications of ISS. Essentially moving from the teacher-centred paradigm to the learner-centred paradigm where assessment is devised based on the student's learning needs and their motivations (Ilvonen, 2013).

Research Approach

This research study outlines the adoption of a blended approach that encompasses both the

traditional approach and the use of social media tools as part of an online game facilitated by IS Security teachers within a university setting. The case selected for this research study was an undergraduate ISS module within University College Cork (UCC), Ireland. This module was selected because of the progressive approach of the associated facilitators to develop, customize, and blend traditional learning approaches and e-learning technologies. The researchers examined the development and implementation of an online game designed to allow students to leverage their classroom acquired know-what in the area of IS security in a simulated 'real world' environment, namely, social media technology Facebook. Table 1 provides a description of the game.

The objective to the ISS Game was to establish a fictitious security company with a social media presence. Data was collected through the student groups, each group submitted a report as the continuous assessment deliverable as part of the overall module. These group reports detailed their communications (e.g. group meetings and communications), and provided an account of their

fictitious company assets, these comprised group generated content including photos, recipes and limericks, and the security attacks made by the company on other groups in the class. This data was analyzed based on the group's ability to leverage the material they learned in class and apply it in the online game scenario, the project outcomes are outlined in Table 2. The performance of each of the groups was reflected in their project grades. Significantly, the feedback on the ISS game from the class was hugely positive, particularly in terms of making, what can be perceived as a 'boring' or far removed topic to undergraduate students, more interesting, engaging, and important. The authors investigated the degree to which the benefits of the game met the learning needs of the students. The analysis also expanded the on-going design of the game to provide an innovative approach to learner support that is more akin to the true essence of social learning. The next sections provide a description of the ISS module and the social game. This is followed by the results of the student's participation and an analysis of the results.

Table 1. Social ISS game description

Student groups are required to form a fictitious security consultancy through, for example, Facebook. The consultancy will be composed of the 6 group members and provide a landing page only viewable to the public and used to document the everyday operations of the consultancy. A hidden section will be used to collect, store and share security resources, tools and information about 5 corporate security breaches. Access to this section of the 'company' will be submitted to the Coordinators.

Students will therefore complete the following, illustrate solutions when appropriate:

1. Create a Fictional consultancy and provide public information about the company and the different (max 6) employees.
2. Select 5 security breaches and critically evaluate / discuss the breaches in terms of:
 - a. ISS Controls before and after the breach
 - b. Business impacts
3. Use Facebook and or Twitter to document the work undertaken to investigate the breaches selected.
4. Compare and contrast the selected 5 or more breaches and the techniques used by the ISS groups to protect corporate assets.
5. Store an asset electronically in the secured section of the Facebook page, on 6 USB keys and printed copies of the page. Create and document the ISS strategy used to protect your corporate asset.
6. A copy of the assets as well as the company details, logins / access to the corporate network and twitter accounts are to be submitted ...
7. Select one or more other student groups to determine if their ISS controls can be bypassed. Document the strategy used by your group to test another groups controls. The strategy used should be documented using a company / group twitter account.

Note: Extra marks will be awarded to the group/company which can obtain a copy of an asset protected by another group. A maximum of 2 assets will be rewarded.

SOCIAL GAMING ENVIRONMENT

This game was created to facilitate and support understanding and learning of the links between ISS and its business applications, essentially to stimulate the 'right' type of learning (Carless, 2007). The creation of fictitious companies and corporate espionage components presented students with the opportunity to play the role of ISS practitioners protecting and simultaneously targeting corporate boundaries in an attempt to acquire and protect assets. At the start of the teaching period 2012/2013, the class (72 students) was divided into teams of 6 members. Each group was expected to meet at least once a week. Project Teams were asked to record minutes of all meetings and day-to-day operations through Twitter and these were kept for review by the coordinators throughout the year (protected Tweets with group and coordinator access). Facebook and Twitter were used to co-ordinate the work effort; thus planning of ISS tasks and workloads well in advance formed an essential element of the overall assignment.

Objective and Outcome of the ISS Game

The game was structured as part of the lecture series (24*2 hours) to gradually build knowledge of the ISS subject domains while simultaneously simulating 'real world' situations when the groups are asked to deliver a series of requirements to determine their level of understanding of the topics (Table 2) discussed in class. Thus following Wilson's (2012) recommendation that if instructors choose to use an active learning environment there needs to be controls in place to guarantee that students are somewhat knowledgeable and prepared before their arrival in the classroom or in this case social media gaming environment. At the end of each assessment submission the goals for the next submission and lecture were set, based on the level of knowledge and understanding demonstrated by students up to that point. Groups submitted and

presented their deliverables at agreed deadlines. This enabled a post-mortem evaluation approach (Kasi et al., 2008). Groups were also required to select 5 security breaches and critically evaluate/discuss the breaches in terms of the controls used before and after the breach. The business impacts were also investigated. These evaluations were then presented and discussed in class. In some instances 3 or 4 groups investigated the same case. However each had their own view regarding how the company reacted to and learned from a reported (published) incident. Case analysis and discussion was the traditional and preferred form of an in-class exercise. This component was enhanced through the use of social media to store documents (reports, articles, videos and slides) and Twitter searches using # to find the discussions which occurred in real-time. Table 2 outlines how these topics were taught, applied, and assessed through the ISS business game.

Student groups submitted their secret/assets at the beginning of the game (Term 1). However while the same technologies, discussed in class and reviewed by the groups, empower ISS practitioners they also empower hackers and hacking organisations to subjugate different types of information systems. This threat became part of the game as students adopted the role of hackers and targeted the secret/asset of another groups to gain extra marks. Thus supporting extant research which suggests that teaching students to defend against IS attacks also develops their attacking skills (Ilvonen, 2013).

Table 3 outlines the results of the hacking component of the game. The groups primarily tried to use man in the middle and password bypass attacks. The most successful attack was conducted by group 1. The group emailed the class using a fake email address from one of the coordinators: Coordinator1@gmail.ucc.ie requesting that students email their secrets before 5pm on the day of the agreed 'secret' submission. 26 students emailed their group's secrets to the fake account. This earned group 1 two extra bonus marks due to the limit of 2 and the fact that by the time the

Table 2. Topics taught and game outcomes

Generative Topics: Analysing ISS requirements; developing ISS strategies; creating ISS plans; ISS controls, computer forensics, compliance, SecSDLC (systems development life-cycle); secure Development, Designing Audit reporting & project management			
Through-lines	Performances	Assessment	Outcomes
How do you address ISS business problems?	Students will understand how to identify assets & allocate the right controls	Related exercises of case organizations	Analysis of Real cases & solutions used to protect assets
How do you identify the ISS requirements of a business?	Students will see the connection between ISS controls & business value	Provide the requirements of a business case	Business impacts of security breaches will be measured.
How should you address analysis requirements?	Students will understand how to analyse problems	Illustrate a logical view of a solution	ISS strategies are selected, discussed & evaluated
How can you use what you have learned to build a solution?	Students will understand the building blocks of an ISS solution	Provide step-by-step guide incorporating a Security life cycle	ISS plan developed
How do you use solve a security breach?	Students will address business & ISS threats, controls & disaster recovery	Provide a fake solution to a security breach based on a case description	Computer forensics of a breach presented
How do you use build an ISS report & apply lessons learned?	Students will understand the skills necessary to convey technical ISS issues to mixed audiences	Feedback on presenting lessons learned from case assessments	Audit review conducted of a selected case
Understanding			
Goals	How to:		
Students will understand the process of 'Forming fictitious ISS companies'.	Submit Company through Facebook , roles, Twitter diary & asset	Emailed to Lecturer early in Term 1	Details of Company, Structure & secret submitted
Students will understand how to apply a divide & conquer approach to an ISS problem	Develop a strategy to protect the group asset. Target other groups to obtain their asset	Presentation through preliminary report & reported through protected tweets.	Full ISS solution submitted for review & feedback
Students will understand how to develop ISS strategies to protect corporate boundaries	Present a walkthrough of the key elements of their strategies: failures & successes	Presentation of solution, with detailed feedback provided	ISS solution presented & reviewed
Students will learn to compete against their peers through ISS bypass attempts.	Students will understand the complete process of protecting & targeting an organization	Construction & presentation of the final versions of solutions.	ISS solution tested internally & externally (penetration tests).

project concluded (despite being consistently targeted by other 11 groups) did not have their corporate secret stolen. This attack was also used to illustrate well published cases of man-in-the-middle attacks. That is despite the fact that this topic was covered during class (2 weeks before

the attack occurred) to the amusement of the majority of the students, due to the simplicity of the attack, 26 students fell for it. This reinforced the importance of controls such as SETA (security, education, training and awareness). As outlined in Table 3 groups were successful in acquiring

Table 3. Attack attempts (Step 7 of Table 1)

Grade	Group	Attack Type	Attempt	Success	Failure	Hacked	Secret Lost
85%	1	Man in Middle	4	26/72	3	4 Org Secrets	None Stolen
72%	2	Password bypass	6	1/72	5	1 Org Secret	None
62%	3	Man in Middle	4	0/72	4	0 Org Secrets	None
68%	4	USB Acquired	2	1/72	1	1 Org Secret	Secret Stolen
75%	5	All Attempted	8	0/72	8	0 Org Secrets	None
60%	6	Password bypass	1	1/72	1	1 Org Secret	Secret Stolen
59%	7	Password Guess	1	1/72	0	1 Org Secret	None
64%	8	Login left open	1	1/72	0	1 Org Secret	Secret Stolen
70%	9	Man in Middle	12	0/72	12	0 Org Secret	Secret Stolen
63%	10	SETA Failure	4	1/72	3	1 Org Secret	Secret Stolen
54%	11	None attempted	0	0/72	0	0 Org Secret	Secret Stolen
50%	12	Password Bypass	27	0/72	27	0 Org Secret	Secret Stolen

another group's asset as well as unsuccessful in protecting their own corporate assets.

In a repeated exercise, conducted with 57 students in the 2015/16 term, Table 4 outlines the number of attack attempts made by individual students and the number of assets the students were able to steal overall, based on 44 survey responses. On average, the students attempted 6 attacks and were able to steal at least one asset, though this varied across the groups.

Figure 1 displays a breakdown of the companies that were attacked during the 2015/16 term exercise. It is evident that some companies were targeted more than others during the exercise.

Of the students surveyed, only some of them showed an awareness of the loss of their asset (see Figure 2). To illustrate this, taking the 44 student responses in Table 4, it was claimed that 61 assets were stolen overall, however, of the 43 student responses about the awareness of this loss, 72% of the students surveyed claimed no loss of an asset and 28% recognised that they had actually lost an asset.

Surveying the students enabled greater insight into the value of the exercise for learning. When asked whether their own attack attempts improved the protection of the group/company's asset (Figure 3), 88% of students (out of 43 responses) replied in the affirmative. Student's had learned through attack attempts how to better improve their own security. For example, one student commented

Table 4. Attack attempts and stolen assets (2015)

	Average No.	Total No.	Responses
Attack attempts	6	258	44
Stolen assets	1	61	44

"We made sure we logged off our computers in the labs at all times when left unattended after getting access to other rival company computer accounts that way". Likewise, different strategies used by students were noted "As we composed a phishing email, it made us more aware that other groups would be doing the same so we were extra careful when receiving emails, correctly identifying them as false".

Discussion

Problem-solving skills require the use of a number of different learning strategies and types of knowledge. In this case, the students leveraged the concepts and strategies considered in the lecture in order to create a fictional company, roles (hacker and security officer), and to apply technical (bypass Facebook controls) and no-technical hacking (social engineering). Students established their secure company and attacked another company/student group using social media. Students were exposed to a number of security threats, enabling them to protect their assets while assuming the

Figure 1. Survey of 44 students (2015): question “what companies did you attack?”

Figure 2. Survey of 43 students (2015): question “was your asset stolen?”

role of hacker. Students became very competitive as they endeavored to steal marks as well as company assets.

The learner’s own experience, internal mental models, and other ‘cognitive structures’ are necessary to ‘construct’ their own knowledge when faced with new information or different situations. This game reinforced the need to recognise that the technical side of ISS is a part of, but not the

answer to, the different ISS challenges. Knowledge and expertise of the technologies are deemed both necessary and valuable in terms of alleviating ISS risks. However in order to achieve this, ISS students must be familiar with critical business processes as well as ISS business impacts. Technological changes, in both secure hardware and software, are as constant as the increase in the number of threats to corporate ISS. Forgetting the most basic

Figure 3. Survey of 43 students (2015): question “did your attacking attempts improve the protection of your group/company asset?”

types of attacks and the potential for employee mistakes are common issues for organisations in general. These errors were experienced by the student groups (Table 3). The mistakes made, as well as adopting the role of hacker, reinforced the material taught in class.

FUTURE RESEARCH DIRECTIONS

In their study Tay and Allen (2011, p. 153) purport that

Staff (educators) saw both the necessity of including greater use of social media in teaching and, at the same time, believed that neither social media technologies themselves, nor the informal and personal cultures of use that students had developed, would necessarily mean that this innovation would – without close attention to pedagogic design – reliably improve students’ outcomes.

While the use of social media technology in this study proved to positively enhance the student learning experience, it is imperative that academia continues to engage with social media technologies in order to further understand and leverage their capabilities, as well as ensuring that this convergence of the traditional and new provides students with a fulfilling learning experience ultimately preparing them for the challenges of

the workplace. Notably this was the first time the game was utilised as part of continuous assessment for an ISS module. The social gaming approach will be used in the future however the lecturers acknowledge the importance of leveraging student grades as part of the student group evaluation process in order move beyond the reported ‘novel’ and positive perceptions associated with the use of social media as part of this class.

Cao et al. (2013) purport that social media is being widely used as a mechanism for learning and assessment in third level institutions. In this study, an assumption was made that students were familiar with social media technology from a social perspective, subsequently they were required to leverage this platform as a means of meaningfully engaging with ISS issues. White et al. (2012) persuade that ISS awareness and education is core to IS education and they contend that this should be supported by education in preventative education and incidence response. The social game presented in this study could be further developed to provide students with the ‘know-what’ and ‘know-how’ to devise preventative security and response strategies.

Like Cao and Hong’s (2011) study of social media utilization in teaching, this research focused on the delivery and assessment of one ISS undergraduate module in one university. In order to further understand the impact of utilizing social media technology as a means of an active

learning approach, a longitudinal study over a number of semesters would be necessary to fully investigate the strengths and weaknesses of this learning strategy (Mikropoulos and Natsis, 2011). Thus, this exercise was repeated with students during the 2015/16 term and preliminary findings were presented along with the findings from 2013/14. This time, students were surveyed after the exercise to better understand the impact of the game on their learning. Overall, students were positive about the learning impacts of the game and were able to identify multiple strategies for attacking and protecting company assets. It would also be beneficial to apply a similar social media gamed-based assessment in another undergraduate programme as a means of exploring the strength of this approach in another setting. It is only then that we can really begin to understand the true impact of the use of social media as part of the active learning approach.

CONCLUSION

It is important that educators begin to place social media technology at the core of IS third level learning and assessment approaches going forward. It is through leveraging these technologies as part of the active learning approach that will better prepare our graduates for the workplace. Undoubtedly, universities and companies face daunting challenges as they compete for the best talent in 2020. They will need to attract new talent, train, retain, and create an engaged workforce. Workers will mainly be knowledge workers, utilizing the Internet, computer technology, communications technology, and knowledge processing platforms as an integral part of their work. Working in physical office spaces with colleagues will diminish, giving way to virtualized teams in distant geographical locations. Third level educators and employers will need to work together to ensure that graduate employees have access to leading edge connectivity tools and the appropriate skills to replace the lack of face-to-face communication.

Organizational leaders are keenly aware that the workplace is changing and are already recruiting a new breed of employee. They are adapting their workplace policies and strategies to appeal to all generations. Therefore IS educators must adapt to the changing needs of industry and students in developing competitive skill-sets through the design of a curriculum that excites students, trains them [IS students] with hands-on exposure, and provides them with the necessary skills to achieve success in the IT industry (Sauls & Gudigantala, 2013). As “current university graduates will become tomorrow’s protectors of data and systems” (White et al., 2013, p. 14).

KEY TERMS AND DEFINITIONS

Information System Security (ISS): The study of defending information, hardware, software resources against unwarranted attack.

Knowledge Workers: A person with a specialized skillset e.g. software engineer, architect, financial analyst.

Online Learning Environment: Online (web-based) channels utilised to support student learning and assessment.

Social Business Gaming: The use of online social gaming as a means of measuring student performance as part of their on-going learning process.

Social Media Technology: Technologies such as Facebook, LinkedIn and Twitter which facilitate user engagement and user-generated content.

Student Assessment and Learning: Knowing what content and skills students have mastered.

Workspace Technology: The platforms and supporting technologies utilised by Knowledge Workers in their day-to-day work routine.

Liberating Educational Technology Through the Socratic Method

E**Frank G. Giuseffi***Lindenwood University, USA*

INTRODUCTION

Digital literacy and technology are instruments for human communication and behavior (Lemke, 2010). The skills and attributes the human person needs for responsible citizenship, and work-performance, is being re-defined by, what Dede (2010) called “information and communication technologies.” In the educational world, November (2012) claimed that a revolution is happening where teachers are harnessing the uses of technology in their courses. Moreover, the influence technology is having on society is fundamentally changing the nature and functions of schools (Lever-Duffy, McDonald, & Mizell, 2010). While one should celebrate the positive results of the role technology has given students in their educational endeavors, our celebration must be tempered with caution. Recent research suggest that suggests that technology, in the form of laptops, has not raised student achievement in any significant way (Goodwin 2011; Hu 2007). If this is the reality that confronts us, we are then pressed to respond. The question for educators is what kind of response? What are the answers to this problem that seems to be growing? This chapter, per the author, suggests that a return to something used in antiquity may be the answer. This chapter explores the use of the Socratic method as a teaching technique that can give direction to the lack of pedagogical vision in the great One to One debate currently confronting schools.

BACKGROUND

In 2009, Arne Duncan, U.S. Secretary of Education exhorted public schools nationwide to implement technology in public schools (Lemke, 2010). He indicated at a national consortium that “good teachers can utilize new technology to accelerate learning and provide extended learning opportunities for students” (Lemke, 2010, p. 245). As one example of this desire to increase educational technology, schools began to invest millions of dollars in One to One laptop programs (Goodwin, 2011).

However, even before this speech by Duncan, issues were raised concerning One to One laptop programs. Hu (2007) indicated that school districts in New York and elsewhere were seeing One to One laptop programs as major obstacles to student learning. As early as 2007, the United States Department of Education found that there was “no difference in academic achievement between students who used educational software programs for math and reading and those who did not” (Hu, 2007). Studies in Texas and Michigan showed mixed results in student achievement when it came to the effectiveness of laptop programs (Goodwin, 2011).

One cannot also discount the influence teaching has on successful laptop programs (Stansbury, 2010). Studies published in the *Journal of Technology, Learning and Assessment* at Boston College’s Lynch School of Education indicated that “the most important factor of all is the teaching practices of instructors – suggesting school

laptop programs are only as effective as the teachers who apply them” (Stansbury, 2010). This is further confirmed from results of a recent study of 997 schools in the United States indicating that one of the factors that added to successful laptop programs was teacher training (Goodwin, 2011).

Hence, educators must seize upon the notion that before laptops are given to students, a commitment to teacher training is needed (November, 2010). Norris and Soloway (2010) echoed this sentiment; they wrote: “To make the computer an essential tool in the classroom, and thus to realize the potential value added from technology, we need to redefine the curriculum in terms of what gets taught, and we need to redefine how it gets taught” (p. 1). Indeed, Pearlman (2010) made the bold claim that simply putting computers in the hands of students is not a solution, but actually “reinforces the old teacher-directed whole group instruction” (p. 127). The common experiences of schools that have embraced laptop programs has been to add on the technology to the same lesson assignments, instead of changing the nature of the lesson assignments. Students have been given the technology, but the lessons have not changed, resulting in the laptop becoming high-priced notebooks (November, 2010).

THE SOCRATIC METHOD

Socrates continually asked insightful questions that reflected the reality that learning came from within (Cookson, 2009). This can be an important teaching technique. As Paul and Elder (2007) noted,

Teachers, students, or indeed anyone interested in probing thinking at a deep level can and should construct Socratic questions and engage in Socratic dialogue. The purpose of using Socratic questioning in teaching may be to probe student thinking; to determine the extent of their knowledge on a given topic, issue, or subject; to model Socratic questioning for them; or to help them analyze a concept or line of reasoning (Pg. 36).

To fully articulate this argument, we first turn to a working definition of the Socratic method. While various definitions exist, the chapter, per the author, puts forth the following,

In the Socratic method, the classroom experience is a shared dialogue between the teacher and students in which both are responsible for pushing the dialogue forward through questioning. The “teacher” or leader of the dialogue asks probing questions in an effort to expose the values and beliefs which frame and support the thoughts and statements of the participants in the inquiry. The students ask questions as well, both of the teacher and each other (Reich, 2003) (P. 1).

The intention is to advance the discussion through dialogue and to uncover, dissect and critically examine accepted positions. This is fundamentally done through thought-provoking and specific questioning. This is clearly the way of Socrates (Cookson, 2009). He [Socrates] would engage his students through questioning and examination of beliefs (Gose 2009; Morrell 2004). This kind of dialectical practice that Socrates espoused leads one to the “good life” (Yengin and Karahoca, 2012). According to Cookson (2009) ultimately, Socrates

Believed learning came from within and that the best and most lasting way to bring latent knowledge to awareness was through the process of continual questioning and unconventional inquiry. For Socrates, answers were always steps on the way to deeper questions (P. 1).

Socratic questions are broken down into basically three kinds: Spontaneous, Exploratory and Focused (Paul & Elder, 2007). The spontaneous question is motivated from a genuine curiosity on the teacher’s part. They are unplanned and arise from conversations that take various paths. Examples could be asking for evidence, asking for others opinions on a given topic, or examples based on a point made during the discussion.

According to Paul and Elder (2007), this kind of question fosters a “Socratic Spirit.” One asks exploratory questions to discover what students are thinking on a particular subject or question. These questions help to broach topics or to get a sense of students’ attitudes or dispositions on a topic. The best and most effective exploratory questions, however, are carefully constructed before the dialogue begins. As Paul and Elder (2007) wrote,

However, for the greatest success some preplanning or pre-thinking is helpful. For example, one could construct a list of possible questions to ask at some point in the discussion. Another preparation technique is to predict students’ likeliest responses and frame some follow-up questions.

Lastly, focused questioning is often done within the context of a larger curriculum, needing to clarify or examine specific issues. The facilitator and students look at a specific topic, subject or idea. The dialogue is more structured and directed (Paul & Elder, 2007).

Let us now proceed to look at the aforementioned types of questions asked based on a Socratic discussion of Aristotle’s *Nicomachean Ethics* in my high school History of Ideas class in the Spring of 2016. We first see spontaneous questioning occur in the following. In Book II, Chapter six, Aristotle wrote,

But not every action nor every passion admits of a mean; for some have names that already imply badness, e.g. spite, shamelessness, envy and in the case of actions adultery, theft, murder; for all of these and suchlike things imply by their names that they are themselves bad, and not the excesses or deficiencies of them (Aristotle, trans. 1941, p. 959).

Teacher: What do we make of this word “shamelessness?” Is shame still a common feeling in today’s society?

Student 1: *The feeling of shame comes from societal pressure. This society prizes individualism. Individuals should not necessarily feel shame if it comes from society’s standards.*

Student 2: *But society’s standards are important.*

Student 1: *Not, however, if it takes away from you as a person.*

Student 2: *You can become a better person from society and having feelings of shame.*

I was initially looking at Aristotle’s concept of the “mean,” however, my interest in “shamelessness” led him or her to ask a spontaneous question on that subject. This then led to further comments on not just shame but its relationship to society and also the importance of the individual.

Staying on the philosophy of Aristotle, the following was an example of exploratory questioning. From Aristotle’s Book II, Chapter 6 of the *Nicomachean Ethics*,

But the intermediate relatively to us is not to be taken so; if ten pounds are too much for the person who is to take it, or too little – too little for Milo, too much for the beginner in athletic exercises. The same is true of running and wrestling. Thus a master of any art avoids excess and defect, but seeks the intermediate and chooses this – the intermediate not in the object but relatively to us (Aristotle, trans. 1941, p. 958).

Teacher: *How does one live morally by finding the intermediate state?*

Student 1: *They don’t go overboard or lend themselves to extremism on a moral issue.*

Student 2: *It depends on the situation you are confronted with. Maybe some things call for extreme measures.*

Teacher: *In what way?*

Student 2: *Well, sometimes governments becomes so tyrannical, revolution is called for. I would say that’s a kind of extremism.*

Teacher: *In a situation like that what would be the intermediate state? In other words, what would citizens who thought the government*

was tyrannical first seek to achieve if they were looking for Aristotle's conception of the intermediate?

Student 1: *Possibly trying to find a compromise with the tyrannical government? I know that sounds a little strange, but maybe those who were feeling abused could work with the government to resolve some of the injustices. Wouldn't that be looking for an intermediate state.*

I explored the issue of "the intermediate" by using moral behavior as an example. Then the discussion evolved into the possible justification, at times, of choosing the extreme.

Lastly, we looked at focused questioning. Here was a discussion based on Aristotle's *Nicomachean Ethics*, Book II, Chapter 7. He wrote,

With regard to feelings of fear and confidence courage is the mean; of the people who exceed, he who exceeds in fearlessness has no name (many of the states have no name), while the man who exceeds in confidence is rash, and he who exceeds in fear and falls short in confidence is a coward (Aristotle, trans. 1941, p. 960).

Teacher: *I am intrigued by the distinctions between courage and rashness. Would coming to the aid of a friend who is being bullied by someone much stronger and larger than you be a courageous or rash act?*

Student 1: *It depends on what you did. I would not use force on someone who is stronger and bigger than me.*

Student 2: *But in those situations one does not worry about oneself.*

Student 3: *Yeah but I am not going to risk my physical well-being over an issue that might be minor. I mean what really constitutes bullying anyway?*

Teacher: *So would it be a rash act to interject in a situation that might cause you physical harm and not be very helpful to the situation?*

Student 2: *I agree that rash acts often counter logic or sense. I would not excuse the scenario you gave. I think coming to the aid of someone even though you may be lacking in some quality is a courageous act.*

I directed the discussion on the differences between courage and rashness, citing an example in order to further illuminate in the students the nature of courage.

ONLINE SOCRATIC DIALOGUE

Studies suggest increased learning in online educational environments that use the Socratic method of teaching (Tucker and Neely, 2010). Moreover, the use of the Socratic method in these same environments bolsters the facilitation of discussion and increased critical thinking skills (Jumper, 2016).

Let us proceed, then, to describe how this can be done in a High School American History class that incorporates an asynchronous, One to One lap top program. In an online learning scenario with each student assigned a lap top, the instructor assigns *The Gettysburg Address*, one of the most well-known presidential speeches in American History; it was delivered by President Abraham Lincoln on November 19, 1863, several months after the three-day American Civil War battle in Gettysburg, Pennsylvania. The speech would be read by attaching a credible, respected History link to the school's Learning Management System (LMS). Prior to the assignment the teacher would have:

- Pretested the students to ensure that previous material had been mastered
- Articulated the learning outcome in specific detail
- Ensured that technologies were available to all students

- Set up content modules for students to use as resources of information (Duffy, McDonald & Mizell, 2010).

Hrastinski (2008) argued that there are three necessary forms of “communications” in asynchronous education the instructor should be aware of: 1) content-related; 2) planning of tasks, and 3) social support. In content-related communication, students (e-learners) must be able to read the assigned content, ask questions, and share their thoughts. In planning of tasks, there are assigned responsibilities, collaboration and conflict resolution. Lastly, in social support, there must be teamwork, positive feedback, and technical support.

In the following examples we will clearly see content-related communication. That is not to say, however, that the Socratic practitioner should not pay close attention to planning of tasks and social support (Gose, 2008). Also, whether in the traditional style of Socratic dialogue or its application in an online program, support for the students is essential. Both instructor and student must be conscious of group cohesion, respect for each other, and emotional support. This will be discussed further in the chapter.

The description of the speech is then followed by three sets of Socratic questions mentioned earlier - spontaneous, exploratory and focused. The exploratory and focused questions will first be presented. These questions can be asked by the instructor for students to ponder and reflect on prior to the dialogue. In fact, having some answers to these questions will help the students develop better spontaneous questions during the dialogue. The following elucidates, through examples, the three types of Socratic questions:

Exploratory

1. What is equality?
2. What does it mean to be “conceived in liberty?”

3. What is the relationship between liberty and equality?

E

Focused

1. What is the “great task” Lincoln is asking the American people to continue?
2. How would you describe Lincoln’s “new birth of freedom?”
3. Do you think this speech does the men who died on that battlefield honor? Why or why not?

Once the students have reflected on these questions, the teacher assigns a time and day for discussion; this is where the spontaneous questioning can take place. The teacher can first ask students about their own definitions of equality and liberty, inviting them to offer specific examples. The teacher can also investigate students’ answers on the connection between liberty and equality – challenging the notion that they are harmonious. This is where the “Socratic Spirit” is developed and a meaningful dialogue occurs. It should be noted that this educational experience would be asynchronous, where teacher and student are not communicating at the same time (Duffy, McDonald & Mizell, 2010). While one could argue that this presents a problem to Socratic dialogue, there are actually positive aspects to this as will be discussed later.

Let us see what that spontaneous Socratic conversation might look like while using laptops via an online discussion board; this platform is where teachers can post information and communicate with students (Ward, 2012). In an asynchronous Socratic dialogue, it is imperative that the teacher set clear procedures and rules. In developing these rules, there will be questions that would need to be answered. For instance, what is the time frame for responding to someone’s question? Also, it will be important to know how frequently each student is expected to post on the online discussion board (Ward, 2012).

The discussion begins with the teacher (facilitator) identified as TCH. Although not indicated on this page, the comments from each individual would include date and time of question or comment.

TCH: *Can somebody offer a definition of “equality?”*

ST#1: *In my mind, equality is the idea that all people are respected before the law.*

ST#2: *I agree, but also that all citizens of a country are protected before the law.*

TCH: *So are both of you arguing that governments or lawmakers grant equality to people?*

ST#1: *Yes, I would. At least a certain kind of equality is granted by governments.*

TCH: *Let us look at the Gettysburg Address again. Lincoln says “dedicated to the proposition that all men are created equal.” Is this implying that the equality that the founders conceived was something they granted or was found in nature?*

ST#2: *I think one can interpret from the document that they are found in nature.*

TCH: *Whether found in nature or granted by governments, the Founders certainly believed these concepts were important to the American Founding. Is there a relationship between equality and liberty?*

ST#3: *Yes. I was trying to come up with a definition of equality that includes liberty. For instance, a regime can promote the idea that all people are free to earn a living, worship in their own way and reside where they want to; this is a kind of equality, isn't it?*

Hence, we see the progression of the lesson take this form:

Figure 1.

With this example, we see a Socratic dialogue about equality via the use of a laptop program. The nature of the Socratic dialogue stays the same as the classical one described earlier. However, unlike the classical conception of the Socratic method, the Socratic method discussion via the Forum is, as we have described earlier, asynchronous - students and instructor can take some time reflecting on a question or comment before they participate. During this “reflective time” students could have re-read the Gettysburg Address, done further research on Abraham Lincoln, or developed better questions for the dialogue. While students are doing this, instructors must be aware of the second form of communication described by Hrastinski (2008), social support. For example, during the reflective time, the teacher could offer positive feedback to the questions and comments that were already asked, present further scholarly analyses by Lincoln scholars, or describe further information on asking insightful questions.

However, it must be noted, that the teacher must be careful not to offer too much information, since he or she runs the risk of disrupting the original topic in the dialogue. Second, students who are not as confident in their speaking ability or who are shy can benefit from using the forum, via their laptops, to voice their opinions. Lastly, students who are apprehensive with their answers can take the necessary time to review and edit what they wish to articulate (Duffy, McDonald, & Mizell, 2010).

In essence, we find four stages that must occur in a One to One Laptop program that uses the Socratic method of teaching and learning. First, there must be a preliminary stage where the lesson is assigned, pre-assessing and frontloading information has occurred, learning objective has been presented and laptops are available to all students. Second, there must be a clear indication of all three modes of communication – content-related, planning of tasks and social support. Third, Socratic questions should be delineated into three question subgroups argued by Paul & Elder (2007) – spontaneous, exploratory and fo-

Figure 2.

cused. Lastly, during the reflective time, teachers must be attentive to giving social support to their students; this will help with content-mastery and achievement.

FUTURE RESEARCH DIRECTIONS

The global possibilities to this educational experience are innumerable. Improvements in communication technologies caused a “death of distance” where the actual physical space between peoples from other countries is made obsolete (Zhao, 2009). Students from all over the United States and the world can participate in a Socratic discussion on the Gettysburg Address, and any other topic in American History. Therefore, it is necessary to continue research on the impact the Socratic method of teaching and learning has on One to One programs. This can be a school-wide initiative or a small sample using action research methods. Questions to consider are:

- Does the use of the Socratic method in One to One laptop programs increase student test scores?

- Does the use of the Socratic method in One to One laptop programs improve teacher pedagogy?
- Does the use of the Socratic Method in One to One laptop programs enhance Self-Directed Learning?

Asking these and other questions will continue the important conversation about teaching, technology and learning in the 21st century.

CONCLUSION

As modern educators, we tend to quickly embrace those things we think will improve student learning. Our faith and confidence in advances in educational technologies is no different. Educators and other professionals quickly invest in the latest technologies to hopefully improve learning outcomes and teacher performance. However, the pre-thinking, and pre-planning that comes with the purchase of these technologies is often set aside or not fully addressed. We should accept that technology like medicine is constantly changing and improving. However, that acceptance is guided by a respect and recognition of those ideas

and educational practices that have informed humankind for centuries. One of those practices has been the Socratic method. We are correct to look forward to the future of technology and the many great things it can offer the world, but we would also do well to capture and hold on to those ideas and practices that have proven beneficial to the intellectual development of humankind.

KEY TERMS AND DEFINITIONS

Alan November: Current writer and theorist on the role technology has on teaching and learning.

Asynchronous: Online education where students and teacher work toward a shared learning objective by communicating with each other at different times.

Critical Thinking Skills: The capacity to understand and analyze ideas through a systematic form of thinking that applies logic, dialectic, self-reflection, and disciplined questioning.

Digital Literacy: The interpretive understanding of technological social networks that create communication and the uses and applications of social media.

Discussion Board: A social network forum that allows for communication and shared inquiry between individuals.

Educational Technology: A description of any learning program and lesson assignment that incorporates technology in its learning outcome and teaching methodology.

Learning Management System: Software programs that capture and documents information for educational purposes.

Socratic Method: A method of teaching that applies a dialectical exchange between persons who wish to arrive at a shared understanding concerning a particular question, thought or idea.

Online Academia

Magdalena Bielenia-Grajewska
University of Gdansk, Poland

INTRODUCTION

The aim of this contribution is to investigate the key notions characterizing the academia of the twenty-first century, especially the sphere of online learning. To present the mentioned relations and complexities within academic learning itself, the *5S Model of Online Academia* has been created and discussed by this author. The proposed model focuses the discussion about online academia on such elements as subject, situation, spirit, stakeholder, senses and subject, and their subcategories, to elaborate on the multilevel nature of universities. This framework provides an insight into the current complexities of online academia and offers an insight into its future perspectives.

BACKGROUND

There are some important factors of modern academia that shape its current state. First, academia is characteristic of its dual nature, it *has been an institutionalized space struggling to secure time for thought, consideration and the slower, time-consuming and lengthy scholarly and scientific conduct deliberately detached from the faster pace of capitalist production, media, politics and their ideological apparatuses; at the same time, it has been a symbol of and an instrument of modern progress, where individual academics and scientists have formed disciplinary associations and alliances, and advocated (to various degrees, and in diverse incarnations), socio-political, economic, scientific and cultural change* (Vostal, 2016: 7). Modern academia can also be discussed by looking at it as a complex adaptive system. It

can be characterized, among others, by nonlinear behavior, visible in disproportionate responses. Other important features of academia are independence, intelligence, learning and self-organization. Moreover, universities are the places of faculty disagreements and different points of control (Rouse, 2016). Academia can also be studied through the prism of its key determinants. Examining the growing role of technology in the life of universities and high schools, non-living entities such as computer systems, hardware, software and mobile technologies determine the way teaching and research are conducted. These notions are studied in the work by Davey and Tatnall (2012) who discuss the notion of technological adoption, focusing on school management software. In the past, traditional dissemination channels were used to gather and share knowledge. Nowadays there are *networked scholars* who use participatory technologies and online social networks in their research (Veletsianos, 2016).

ONLINE ACADEMIA- KEY ELEMENTS AND CHARACTERISTICS

Modern education differs from what could be observed some years ago; teaching and learning of the twenty-first century involve not only various learners in terms of their age, gender and background, but also diversified methods of encoding and decoding knowledge. As has already been mentioned, modern academia relies on technology in all spheres of activity. Murphy, Kalbaska, Horton-Tognazzini and Cantoni (2015) discuss in their contribution four categories of online learning: resources, tutorials, courses and

MOOCs. Apart from different materials and tools used in online learning, one of the key notions is connected with *online ludic corporate identity*, represented in the growing popularity of ludism among the broadly understood stakeholders. It is visible in, among others, fun and relaxation that accompany shopping or telling jokes and funny stories by workers (Bielenia-Grajewska, 2016). Analysing the sphere of teaching and learning, *ludic academia*, responding to the needs of stakeholders, is connected with using, for instruction, the tools associated in the past exclusively with leisure activities. One example is the application of online games in teaching and learning. Since games are not associated with spending free time as it was in the past, the appearance of serious games has changed instruction in the twenty-first century. The usage of serious games can be examined by using the 5P Model of Studying Serious Games (Bielenia-Grajewska, 2016). The first element is called *Problem-solving* and is connected with information processing and decision making. In the case of educational games, it can enhance the capacity of students to analyse and make decisions in virtual reality. The second notion is *Personae*; and is connected with elements reflecting organizational identity. In the case of educational games used for academia, verbal and non-verbal representations create the identity of a given university and show its mission and vision. The third element- *People*- stresses the lack of fixed hierarchy in games and interactions among people representing different levels on the real organizational ladder. Thus, serious games may be the place where students and professors interact in a more informal way. The next notion is called *Proficiency*; serious games are often offered in both synchronous and asynchronous ways, in a relaxed atmosphere and, consequently, their efficiency is higher than standard learning tools. The last element is *Persuasion*. Since the purpose of serious games is to advertise products or services or to evoke certain behaviours, they can be used

effectively in academia to attract new students or make current learners more interested in the instruction. For example, with the appearance of MOOCs and other educational offers available online, modern education is not restricted in terms of geography, prior levels of knowledge or types of accessible educational tools as it was before. Consequently, learners, teachers and instruction environments of the twenty-first century fail easy categorization. As has been mentioned earlier in this contribution, e-universities have become more and more popular nowadays. The reasons for this are mainly connected with technological development, including the growing popularity of the Internet, and the consequent needs and expectations of stakeholders towards educational services. Thus, nowadays students have the opportunity to have their courses run on educational platforms (e.g. Moodle), take part in massive online open courses (MOOCs) and participate in webinariums or chats with professors. The access to these resources is open or restricted only to the students of a given university or the participants of a given course. Although open online courses have many advantages, offering education to all interested in learning, Schulze, Leigh, Sparks & Spinello (2017) draw attention to the fact that MOOCs are characterized by low completion rates, taking into account the high number of registered users. Apart from MOOCs, gamification is used in online academia. It is defined as using the techniques and thinking characteristic of games for making people behave in a given way, promoting some learning styles and solving problems. In the sphere of education, such elements as points, virtual awards or leaderboards are used in courses to stimulate the interest of students in the learning content (Bielenia-Grajewska, 2015b). It should be mentioned, however, that apart from concentrating on education directed at many participants, online learning also focuses on individuals at the same time, offering online tutoring and mentoring (Berg, 2010).

5S Model of Online Academia

To study the complexities of offering tuition on the web, the 5S Model of Online Academia has been created and discussed by this author. The author has presented the key elements of modern academia (present in both its online and offline versions), studying their role in education by paying special attention to e-learning.

SUBJECT

The first element of the studied model- Subject- includes what constitutes the topic of learning. Subject is connected with students' interests, needs and expectations towards the curriculum, with such frequent sub-notions as *salaries*, solutions, stepping stones, skills and schemes. Starting with salaries, selecting subjects is often connected with discrepancies in remuneration levels and the potential increase in salaries together with one's higher skills or experience. Salary may also be the determinant of choosing a course for vocational training, with not the best but the cheapest option

being selected by participants. *Solutions*, on the other hand, encompass the ways problems and challenges can be dealt with. They stimulate a better understanding of the topic. In the case of online learning, solutions are often discussed in forums or chat rooms. *Stepping stones* are connected with stages of accomplishing educational goals. In the case of online courses, they often mark the level of knowledge acquired in a given stage and in a given period of time, or one necessary to embark on a new learning stage, in a way forcing students to learn systematically. *Skills* also constitute an important aspect of learning. In the era of online schooling, people can gain new knowledge also on the net, without leaving their houses or offices. The restrictions related to geographical barriers do not apply to the same extent as in the past, with the material ones being relevant also only to some extent since many online courses are offered free of charge. *Schemes* are related to consecutiveness in education. The necessity to repeat knowledge is solved in e-learning. Online courses are effective for novel and complicated materials that require repetition since students can listen to the tape or watch the video as many times as necessary.

Figure 1. 5S model of online academia (created by this author)

SITUATION

Situation is broadly understood as the learning environment. From the micro sphere, it can be understood as a course or class, whereas the more macro approach focuses on learning policies and pan-national regulations. It envelops source, saturation point (of information), season, scene and 3 *Situational S-components*: Storm, Silence and Struggle. The first sub-element is *Source*, being connected with the origin of a given situation. It encompasses the reasons why something happened. In the learning context, it can be connected with the rationale why someone wanted to start a new course or the whole curriculum. The next one is *saturation point*, being linked with the amount of information that has so far been available for future students; the knowledge they possess determines their interest in engaging in the offered type of schooling. In addition, an offer that in a way exceeds the mentioned saturation point and does not evoke any interest among the target audience is substituted with the more novel one. Saturation point may also be treated as the number of professionals possessing this educational profile and already present on the job market. *Season* is associated with determinants related to time of day, days, months and other time-related factors connected with how different notions determine organizational performance. For example, daily students usually study from Monday to Friday, with most of their courses planned for mornings and afternoons, whereas extramural students usually frequent courses during weekends or evenings. In comparison with standard forms of teaching and learning, online courses offer the possibility to study when one can and wants, taking into account time differences and one's professional duties or household chores. Even if a webinarium is planned, students who cannot attend it synchronously can later watch the recorded video. *Style* reflects the way one deals with knowledge, with the way instruction is coded and decoded. In the case of education, teacher's style may determine the way a given matter is understood. When the manner

of instruction is not favored by students, even a simple matter may be difficult to follow. It holds especially true in the case of online learning when it is difficult to observe if students are interested and pursue their studies without the control of an instructor. *Simulation* is connected with causing certain reactions, usually among learners. When a response is caused, then more complicated forms of interaction can be made. Traditional and online courses should stimulate participants to search for new sources of knowledge, to find answers for their queries and to pose new questions. *Scene* is connected with the geographical location of learning, determining when interaction takes place. In the case of online instructions, scene is not linked to one geographical location. An online course has an Internet address in order to be found in the web jungle. Learning may also be discussed through the prism of 3 *Situational S-components*, such as *Storm*, *Silence* and *Struggle*, mainly mirroring the type of situations in learning, with silence used to denote unproblematic conditions and standard ways of interactions. Storm, on the other hand, depicts crisis or changes in organizations offering tuition or among students or teachers, with struggle used to describe teachers' or students' engagement in protecting their workplace and place of study.

E

SENSES

Senses encompass such notions as Speech, Scent, Sound and Sign. *Speech*, being the verbal representation of communication, can be sub-categorized into standard communication, slang and symbolic language. Standard communication includes accepted forms of interaction, being used in everyday performance of organizations. It mainly encompasses literal forms, making it possible to express one's point of view effectively. In addition to standard forms of communication used in teaching, students and teachers often rely on symbolic language, allowing for a more subjective type of expression. The mentioned figurative interaction encompasses metaphors, metonymies,

and allegories. In addition to literal and non-literal dialogic representation, students and teachers rely on slang or professional dialects. Since the verbal sphere of education constitutes the most often used channel of communication, attention is paid to the way words determine modern instruction. This thought can also be used to discuss the introduction of new terms in any discipline, showing, for example, how, among different linguistic tools, metaphors play important functions in managing knowledge. Relying on well-known domains, they are effective in coding and decoding knowledge. Analyzing specialized communication, professionals relying on symbolic language communicate quickly and effectively. Since metaphors offer efficient communication, dense in terms of signs and words used, it turns out to be effective in online communication that is connected with being economical in using linguistic representation. Metaphors are also important at the organizational level, showing the profile of company activities and organizational culture (Bielenia-Grajewska, 2015a). The performance of refreshing the mind is connected with several ways the application of metaphors in modern teaching can be understood. One method is to look at symbolic language from the learners' perspective. Metaphors make complicated and novel concepts easier to understand since they relate to well-known concepts and phenomena. In addition, metaphors make the teacher's profession interesting; teachers searching for new metaphors in their instruction make their own job adventurous. The next sense- *Scent*- is associated with the olfactory dimension of communication and learning, represented in sensory marketing, with things like special scents characteristic of educational settings. This dimension may also be a part of a given lesson, such as one devoted to presenting some dishes representative of a given culture. In the case of online learning, scent has to be substituted with other forms of expression, often relying more on words and sounds to evoke similar feelings. *Sounds* represent the auditory sphere of educational interactions. In the case of online learning, the speed of online connection

determines the quality of voice. *Signs*, although they can have different dimensions, are often used in the pictorial sphere of representation.

SPIRIT

Spirit is connected with learning atmosphere and teaching rules. The first approach to learning spirit and its role for online instruction can be studied through such notions as Standards, Sanctions, Space and System. *Standards* are mainly understood as the set of rules and expectations that both instructors and learners have to meet in order to fulfill their roles. At the micro level, it is connected with respecting regulations connected with frequenting online courses, such as punctuality in the case of assignments, observing net etiquette on forums, etc. *Sanctions*, understood as an element of social control, are discussed through the prism of violating classroom codes of behavior and the consequences related to these acts of negligence. In the case of academia, they may result in suspension or relegation. *Space* is connected with the arrangement of learning place. In the case of academia, traditional universities are often supplemented with virtual classrooms. *System* can be researched through the notion of learning culture. Examining academia, it may be university culture that is recognized by both learners and instructors. There are different types of learning culture that do not foster knowledge exchange. One of them is *sweep learning culture*, observable in educational organizations that do not face problems and do not solve them, but rather only try to survive till the semester ends. This sort of atmosphere facilitates dissatisfaction of students and learners, being represented especially by a high rate of dropouts. Another type of learning spirit is *surface learning culture* that is superficial and does not rely on deep values. In this case, only basic materials are offered, with the lack of student immersion into the broader context of disciplines. The next type is *stream learning culture*, following the most popular model

of teaching and running organizations, built on widely accepted rules and values, and likely to be met in many learning entities. In the latter one, there is limited place for own ideas and creativity.

STAKEHOLDERS

Stakeholders constitute the last dimension that can be divided into inner and outer subtypes. As far as subcategorization is concerned, the inner dimension encompasses *Staff* (teachers, school owners) and *Students*, whereas the outer one can be classified as *Shoppers* (encompassing the ones searching for educational offers before making decisions); both groups may be viewed through the perspective of status. *Status* may reflect such notions as one's position within a studied hierarchy. In the case of staff, it concerns one's place on an educational ladder, whereas shoppers are often labelled by taking into account their social or professional position and potential interest in the offered educational products or services.

FUTURE RESEARCH DIRECTIONS

Manning, Wong, and Tatnall (2010) discuss that nowadays many universities combine traditional learning with e-learning platforms, using both face-to-face interactions and distance instructions. It can be expected that in the future even more courses will be offered online, taking into account the expectations and needs of students who prefer online learning or their geographical location does not allow them to study in a traditional way. Moreover, Sancassani, Casiraghi, Corti and Trentinaglia (2014) stress the role of MOCCs in improving the quality of traditional learning as well as its cost. Taking the last money-related factor into account, it can be predicted that more educational institutions will be interested in offering instruction that is characterized by economic efficiency for both educators and students.

CONCLUSION

The growing popularity of technology and diversified demands and expectations of academia stakeholders have led to crucial changes in the way universities perform nowadays. As has been discussed in this contribution, online academia is connected with offering its tuition and running its communication on the Internet. The proposed model offers a complex insight of how online academia can be investigated.

E-Learning: Learning by using tools and materials available online.

Online Academia: Teaching and learning conducted by the stakeholders of the academic world on the Internet.

Online Learning Propelled by Constructivism

Kathaleen Reid-Martinez
Oral Roberts University, USA

Linda D. Grooms
Regent University, USA

INTRODUCTION

Augmenting communication in and among those in the academic, business, and military communities, the exponential advancement of science and technology has availed vast amounts of information to virtually millions of people around the globe. In conjunction with this knowledge explosion has been a growing concern for the democratization of the learning process, with constructivism driving much of the educational agenda, most particularly in online distance education. This article examines the resurgence of the constructivist approach to teaching and learning, its convergence with rapidly changing technological advances, and its relationship to future trends in online pedagogy.

BACKGROUND

While the constructivist method has been highly emphasized in the recent literature for online distance education (Brown, L. 2014; Bryant & Bates, 2015; Holzweiss, Joyner, Fuller, Henderson, & Young, 2014; Lê & Lê, 2012; “Learning Theories”, 2014; Mbatl & Minnaar, 2015; Symeonides & Childs, 2015; Thorne, 2013), it is not a new approach to learning. Presenting an early example, Socrates facilitated discourse with students asking directed questions to assist them in realizing the weaknesses in their logic and critical thinking. This enabled learners to share in the responsibility of their learning through active participation while

negotiating meaning in the creation of shared understanding. In contrast, medieval professors in later Western culture most often served as primary repositories of information along with the scrolls and velum texts found in the limited number of physical libraries available to educators. With the lecture serving as the quickest and easiest way to disseminate information to both small and large groups of individuals, it was both an efficient and effective delivery method in the shaping and forming of student knowledge, quickly becoming the standard for traditional education.

MAIN FOCUS OF THE ARTICLE

Resurgence of Constructivism

While the lecture method was the norm of information delivery for centuries in Western culture, the knowledge explosion arising from the latter part of the 20th century demanded more active learner participation. In light of this constant and rapid flux of information and knowledge, students became life-long learners compelled to use metacognitive skills to constantly evaluate and assimilate new material into their respective disciplines. As this implies, knowledge was no longer viewed as a fixed object; rather, learners constructed it as they experienced and co-created an understanding of various phenomena by collaborating and working with peers and professors as well as with the information. Now, rather than strictly acquiring

DOI: 10.4018/978-1-5225-2255-3.ch226

ing information, Duffy and Cunningham (1996) explicated that “learning is an active process of constructing ... knowledge and ... instruction is a process of supporting that construction” (p. 171).

Based on the work of Kidd (1973), Long (1983), Moore (1989), and Palmer (1993), Grooms’ (2000) *Learner Interaction Model* (see Figure 1) illustrates that in the constructivist culture, the learner perpetually interacts with these three components of learning--content, facilitator or professor, and peers--each mutually and non-discriminately influencing the other.

Critical in this process is recognizing the shifting role of the professor who becomes the *guide on the side* or content facilitator and is no longer the proverbial *sage on the stage* or content provider. The student’s role also has changed from being a passive receiver of information to an active participant in the knowledge-making process (Weller, 1988), aligning with Bandura’s (1977, 1994) concept of the autonomous learner, an important dimension of the constructivist model. Table 1, based upon an earlier model from Reid-Martinez, Grooms, and Bocarnea (2009) and Reid-Martinez and Grooms (2015), delineates these two approaches to learning.

Of special interest in the above listing is the role of community. The constructivist approach

recognizes that students do not learn strictly within the limited confines of a local educational institution, but rather within the broader international and global context of their personal lives extended through social media and multiple technologies. Consequently, the boundaries between the educational institution and the larger community become blurred creating its own unique set of opportunities and challenges.

As people work collaboratively in the learning activities and new technologies, they bring multiple worldviews and experiences to each situation often creating a plethora of perspectives. During this collaborative learning process, they must negotiate and generate meaning and solutions to problems through shared understanding. Thus, education moves from a single, solitary pursuit of knowledge to a collaborative learning community that shapes and informs responses to the environment. As noted by Fuller and Söderlund (2002), this challenges the common metaphor of the university as a self-contained village.

Rapidly Changing Distance Learning Technologies

Over the years, educators have experimented with and successfully employed multiple media for

Figure 1.
2000 Grooms, L. D.

Table 1.

Approaches to Learning		
	Traditional	Constructivist
Professor	Sage on the Stage	Guide on the Side
	Content Provider	Content Facilitator
Learner	Passive Recipient	Active Participant
Knowledge	Fixed Object	Fluid
Organization of Learning	Ordered & Structured	Open & Often Chaotic
Communication	Uni-directional	Multi-directional
Primary Resource	Text & Professor	Multiple Sources
Method	Lecture	Active Process
Media	Print	Blended
Format	Structured & Individualized	Adaptive & Collaborative
Activities	Goal-Oriented	Problem-Centered
Focus of Learning	Knowledge & Understanding	Application, Analysis, Synthesis, & Evaluation
Assessment	Recall	Alternative Assessment
Community	Local Educational Institution	Integrated with Life in Global Contexts

distance learning, and today, as much as in the past, they continue to stress that pedagogy must drive technology (Rourke & Coleman, 2011). As early as the 18th century, print material was used and even today still serves an important role in distance education even as it gives way to more reliance on technology and web-based resources for collaborative development of knowledge that incorporates the diversity of learners and their contexts. After the 1930s, other media became significant with audio--including radio and audiotapes--and video--including film, public broadcasting, and cable--dominating much of the 20th century.

Much of this education was one-way based on a mass communication or one-to-many educational model. Basically, it was a rigid structure with information flowing in one direction, from the powerful and knowledgeable instructor reaching to the individual or even the larger group of students. It included elements of limited feedback through the use of such things as the penny post in the 19th century and the addition of the telephone and fax in the 20th century. Limited opportunities for face-to-face interaction were also incorporated

with some programs. Thus much of distance learning during these times remained mainly non-interactive.

By the 1990s, the advent of the Internet presented new opportunities in distance education. The result was the evolution of a new type of collaborative learning, in which the potential for interaction between the professor and the learner increased exponentially with wide-area networks accommodating synchronous and asynchronous communication. While exploring computer-mediated activities of the online learning environment, Santoro (1996) highlighted three broad categories: (a) computer-assisted instruction, which allows the computer to serve as “teacher” by structuring information delivered to the human user; (b) computer-based conferencing, which includes e-mail, interactive messaging, and group conference support systems; and (c) informatics, which refers to online public access libraries and interactive remote databases. This proliferation of the Internet unlocked the door for educational institutions to reach beyond their four walls making services accessible to students around the world through online activities.

Although the communication technologies of the 21st century--print, audio, video, digital, and the Internet--cover a broad spectrum of distance education mediums, this exponential growth in science and technology has catapulted the Internet into rapidly becoming the preferred delivery platform. Since 1995, researchers such as Cotton (1995) and others have been tracking this information along with scholars such as Bocarnea, Grooms, and Reid-Martinez (2006), Grooms and Reid-Martinez (2013), and Reid-Martinez and Grooms (2012, 2015). They continue to explore not only the trends in distance education but also the understanding of and the issues involved in aligning the environment with student needs. Typical factors include (a) the characteristics of the discipline, (b) the degree of interactivity sought in the distance learning process, (c) learner characteristics, (d) instructor traits, (e) the expansiveness of the distance education initiative, (f) the desired level of accessibility and flexibility related the delivery capacity of learning platforms and smart mobile devices as well as other methods of dissemination, and lastly (g) the availability of technical support.

In addition to the global reach of the Internet, the lines *among* communication technologies have swiftly blurred. Today in the convergence of technologies, computers, telephones, and cameras are no longer distinct entities, but can be found bundled into one small handheld gadget through the fusion of technology (McCain & Jukes, 2001). These smaller fused devices create more mobility and simultaneously provide mixed realities through virtual immersive environments embedded within traditional spaces. Continuing advances, such as that found in interactive optical sensory technology, feed this growing world that fuses the virtual with the physical (Rolf, 2012). Through this fusion, communicating with students and colleagues has become more instantaneous, integrated and complex. While vastly expanding the means of interaction and feedback, it demands greater capacity and understanding of the multiple communication modalities.

Connected to these new technologies is the capacity to enhance adaptive individualized learning. As noted by Allen and Seaman (2013), adaptive learning helps overcome the barriers to online learning, a common concern of many academic leaders. As we see in the research of such scholars as Yang, Gamble, Hung, and Lin (2014), critical thinking can be enhanced through adaptive learning in the online environment. These new adaptive learning technologies accelerate and enhance learners' problem solving ability. The fusion of technological capacity for adaptive learning with collaborative technology platforms results in individuals operating at a more advanced level and collectively harnessing greater learning and problem solving abilities from all participants.

With such rapid technological advances, today's educators are dropped into what Jacque Ellul (1964) described as the intersection of tension between humanity and technology. This struggle with the latent and manifest, intended and unintended consequences of technology exists as students and professors wrestle with cloud computing, three-dimensional immersive learning environments, and other rapidly expanding web opportunities.

Such technology facilitates greater flexibility and customization in the learning process. Lead Learning Designer at IBM, Don Morrison (2004) demonstrated how the learning process can be established within parameters and policies that most appropriately align with the primary strengths and weaknesses of each medium. He noted that among others, cost, time constraints, delivery speed, and infrastructure help determine appropriate application. Morrison's work also pointed to ways in which educational models can be designed to marry traditional and online means of moving from the simple to the more complex methods of learning.

As the above suggests, these new electronic forms of communication have forced a paradigm shift in education. This move is most avidly seen in distance learning, where even the terminology has shifted from distance education to words such

as online or e-learning. Such terms more clearly indicate the way in which learners can use multiple media to easily collaborate through a continuous integration of knowledge and social capital.

FUTURE RESEARCH DIRECTIONS

As previously discussed, the rapid growth of technology continues to herald unprecedented opportunity for distance learning, and when wed to a constructivist approach, it presents opportunities for online pedagogy that can transcend traditional modes of education. From this marriage emerges three primary factors that define the new online pedagogy: (a) *community* development--the ability to build networks and communities that cross time and geographic boundaries, (b) *structure*--the technological ability to manage vast amounts of information, and (c) *collaborative* opportunities--for shared knowledge and wisdom building in response to the complexities of a global society (Reid-Martinez, 2006).

Community

As Bocarnea et al. (2006) note, today's technologies launch a new paradigm of online learning and pedagogy, which has the potential to be communal in nature. Primarily, these technologies allow for interaction between students and professors, students and peers, and the broader community in unprecedented ways. For example, students today have greater instructor and peer access through social media and e-learning platforms. Indeed the study of mobile technology for learning in environments of high action and great distance as found in the work of Black and Hawkes (2011) points to the now even more ubiquitous capacity of mobile learning (m-learning). In turn, this poses the question of expectation--whether conscious or not--regarding ubiquity of instructor presence and community development. It also enhances the ubiquity of the student in the learning process. Indeed, learning is no longer "just in time," but

with adaptive learning and other capacities that allow for learning that is "just for you" and "just with you" through wearable smart devices and other advancing technologies. This contemporary and developing technology now allows learning to be fluid with the learner in a simultaneous and continuous nature (Reid-Martinez, 2015).

These new technological advances raise the question of boundaries in the learning process. While advancing technologies provide unprecedented opportunities for networking and building strong virtual learning communities, they do transcend geographical boundaries and normal hours of operation as well as far beyond the duration of students' formal education. As early as 2002, Young highlighted the differences between the boundaries embedded in his traditional face-to-face class and that which he encountered online. This suggests that guidelines following best practices to manage the continuous nature of virtual learning experiences are essential to prevent online instructors and students from feeling overwhelmed by the 24-7, ubiquitous opportunity for interaction.

In addition, this communal nature of the virtual learning environment provides opportunities for students to bring their local community contexts into the learning experience in direct ways as well as immediately allowing them to apply what they have learned through their study. For example, students in leadership programs can be employed full-time in leadership positions and take their learning experiences directly into their work environment through well-designed course assignments. The professor is no longer someone whom the student must wait to see in class later in the week, but rather is readily available in e-learning and m-learning platforms to serve as consultant and mentor as the student applies the principles studied that week. The professor has become the *guide on the side*. This triangulation of student-professor-content points to the need for well-designed learning experiences developed from a constructivist perspective to meet the challenges and needs of today's students. Indeed, unit-

ing the new technology with this approach meets the needs of contemporary students working in rapidly changing and highly demanding global environments.

Additionally, rapid advancement of technology creates a moving target challenge for course developers who often find themselves reacting to the technological advances rather than proactively establishing the technology's relationship to the learning process. While scholars such as Schweizer (1999) noted unsound pedagogy and inadequate design in early online courses, others such as Wang and Newlin (2002) reinforced the importance of incorporating the opposite as critical predictors of successful student performance. Just a short time later, others such as Beetham and Sharpe (2007) and Rourke and Coleman (2011) continued to reinforce the critical role of pedagogy in using technology. Such approaches assure that good pedagogy is the driver of learning, not new technologies. This helps resolve Bocarnea et al.'s (2006) observation and concern that theory typically "follows technology in desperate attempts to describe the impact of an already existing and rapidly fading ... technological reality" (p. 385).

This posits that staying focused on strategy and content design remains the dominant challenge. Online pedagogy, the science *of* and *about* online education, provides perspective to assist in focusing and maintaining the balance necessary for creating excellent online learning experiences.

Structure

Heralded just over 20 years ago by Negroponte (1995), the information age is collapsing on itself as the amount of online information is becoming unbearable. After the scramble to have everything digitized, the primary challenge today is how to create meaningful knowledge from such massive amounts of data. Quality of knowledge, in contrast to quantity, drives the heart of this concern. In light of this overload, *structure* is essential to online knowledge development.

Related to structure, is the development of open-source initiatives. While most often understood as the software that is open for use and modification by the public, the phrase has become a recognized attribute ascribed to multiple endeavors, such as knowledge-building. The open-source nature of online initiatives pushes a new model for managing learning and knowledge-building through the communal process. It allows diverse individuals from various locations to combine information from multiple sources into distributed knowledge networks. Through this open-source structure, participants interact to share experiences and knowledge, thereby expanding their awareness of new concepts and differing approaches to problem-solving as they modify the information in the open-source environment and re-distribute it back to fellow participants (Bocarnea et al., 2006).

As this suggests, through interaction, participants build complex webs of knowledge in the open-source cyberspace. The technology provides the structure to create and maintain webs of knowledge, and it also grants ease of access globally to those interested in that knowledge. In the process, knowledge is given away to others who in turn begin to use it in multiple ways while beginning the next evolution of knowledge development as they add to and transform the knowledge base they accessed through the open-source structure. With this transformation through this structural capacity is the transference of power and control that becomes less centrist and more distributed globally.

Collaborative Knowledge-Building

As noted above, interaction is the key for the development of open-source knowledge-building. While scholars such as Cederbom and Paulsen (2001) posited learning as a behavioral change, others hold that it is simply when learners meet needs and establish goals for attaining knowledge (Ponton & Carr, 2000). Referring to this process as an implied contract, Keirns (1999), along with the above scholars, suggested that if online learn-

ing is used, structure is critical to allow students to advance in their knowledge.

Because “engaging the learner in reflective and collaborative thought processes ... results in the most effective learning, whether the setting is a traditional classroom or an online environment” (Cox & Cox, 2008), the design of the online course becomes the principal structure to assure learners’ goals are achieved. In that course design, one way of attaining the collaborative thought processes is to incorporate structured interaction. Not only does this interaction provide for collaborative thoughts and knowledge development, it provides multiple opportunities for faculty to prompt students’ critical thinking. In keeping with this, researchers such as Pelech and Pieper (2010) went so far as to clearly lay out, among other approaches, the roles of visual literacy, bridging questioning, and kinesthetic activities in applying Bloom’s taxonomy for constructivist learning.

While these dimensions of critical thinking undergird contemporary collaborative capacity in online learning, other psychological dimensions are becoming more prevalent in understanding how critical thinking and collaboration can increase. For example, Rolf (2012) surfaced the complexities of virtual collaboration in his study of contemporary technologies’ role in creating mixed realities. Another example is Mabrito’s (2011) study of vicarious interaction--that is, observing not participating in peer as well as faculty-peer online interaction--which can generate more idea awareness in a constructivist learning environment and has potential impact on how collaboration occurs.

A common way to collaborate in the online environment is through interaction. Blair (2002) suggested that stronger relationships are forged through increased interaction frequency. Increased interaction relates to higher learner commitment due to the socialization the learner experiences as a participant in the knowledge-building process. Thus, learner perception of interaction plays an important role in student achievement, satisfaction, and quality of learning.

Again, in the collaborative nature of the constructivist online culture, interaction perpetually occurs between learners and content, learners and instructors, learners and peers, and learners and external experts with each type of interaction reinforcing and fostering collaborative knowledge-building. Teaching disappears and “communication of information rules, where information is available to all and in abundance” (Brown, T. H., 2015, p, 228). With this in mind, online course design must include best structures to capitalize on this collaborative interaction.

CONCLUSION

As the above suggests, the advent of online learning education has not just provided opportunity to disseminate information in a new medium, it has radically adjusted the distance learning paradigm in terms of distribution methods, community building, knowledge development, and learning. The use of 21st century technology is rapidly closing the gap of the communication immediacy essential in developing communities of practice for knowledge-building. With their open-source networks, these new technologies encourage and actively support constructivist pedagogy in the distance education paradigm. Most of all, distance education through its constructivist pedagogy and contemporary technologies has the technical capacity to fulfill its greatest potential, which is to reach every learner who desires to participate in the knowledge-building process. The result can be a democratization of education not previously seen, allowing for shifts in power and control throughout societies.

KEY TERMS AND DEFINITIONS

Autonomous Learner: An individual who takes responsibility for his or her learning.

Collaborative Learning: The process in which individuals negotiate and generate meaning and solutions to problems through shared understanding.

Computer-Assisted Instruction: The computer serves as the “teacher” by structuring information delivered to the human user.

Computer-Based Conferencing: E-mail, interactive messaging, and group conference support systems.

Constructivism: An approach in which students share responsibility for their learning while negotiating meaning through active participation in the co-creation of shared understanding within the learning context.

Distributed Knowledge: Information dispersed throughout a community of practice and not held by any one individual.

Informatics: Online public access libraries and interactive remote databases.

Interaction: mutual communicative exchange between individuals.

Science Animation and Students' Attitudes

E**Sivasankar Arumugam***Sri Venkateswara College of Education, India***Nancy Nirmala***Christ the King Matric Higher Secondary School, India*

INTRODUCTION

Teaching is a kind of social engineering that does not deal with lifeless machines and hard wares; it cultivates tender minds into brave hearts that in turn with brimming confidence is going to build the society. In this endeavour every student is important, every detail present in each topic is essential and every batch of students is precious. The digital transformations that are taking place in educational arena had opened newer avenues for the teachers, learners, administrators and researchers in the form of animation. Animation in its own virtue along with enthusiasm of digital native learners had grown leaps and bounds. The need for animation in third world countries seems to be pinning as teacher- pupil ratio is alarmingly high when comparing with many of the Western counterparts and majority of the education machinery is examination ridden. When the teacher has to run behind the content and ensure zero failure it becomes imperative to teach science with animation. And the metamorphosis that animation could take as per the projection of experts is very promising. This study makes an experimental approach with science animation in secondary school classes and its impact through achievement and attitude.

Meaning of Animation

Etymologically animation has got Latin origin animatio from animare which means the condition of being alive or giving life. Rapid display of images, pictures or frames is called as animation.

The technique of capturing successive frames of pictures or positions of toys or models that create an illusion of movement while the movie is shown as a sequence gives life to animation. In other words a collection of static images joined together and shown consecutively so that they appear to move is called as animation.

Evolution of Animation

Animation's origin can be tracked right from 1824 with the wide usage of thaumatrope that was largely given credit to John Aryton of Paris. Since then the field of animation had experienced various meaningful adaptations and thereby can be classified into three wide verticals namely (i) Traditional animation, (ii) Stop frame animation and (iii) computer animation (2D and 3D). Traditional animation includes Thaumatrope, Phenakistoscope, Zoetrope, Flip book, and Praxinoscope.

Thaumatrope

In early 19th century, Thaumatrope was very popular. Etymologically Thaumatrope has got Greek origin Thagma meaning marvel and tropos meaning turning. Two pieces of string with two different pictures on each side, like as a tiger and a cage, is attached to a small disk. Twirling of strings quickly between the fingers seems to combine into a single image. This is due to persistence of vision, the physiological phenomenon that ensures imagery rests in the eyes and brain for a small fraction of a second even after the vision is blocked or the object is removed.

DOI: 10.4018/978-1-5225-2255-3.ch227

Figure 1.

Phenakistoscope

Phenakistoscope was the earliest animating device invented simultaneously by Joseph Plateau of Belgium and Simon Von Stampfer of Austria in the year 1831. In Greek Phenakezein means to deceive or to cheat. It composed of a disk with series of images pasted or drawn on radii of the disk at different distance from the centre. The Phenakistoscope would be placed in front of a mirror and rotated. While the phenakistoscope rotates, a viewer can look through the slits at the reflection of the drawings that are visible like a flash when a slot passes by the viewer's eye and ensures the illusion of animation.

Zootrope

William George Horner in 1834 suggested the concept of Zootrope. Etymologically Zootrope has got Greek origin Zeo meaning life and tropos meaning turning. Zootrope literally means "wheel of life". The principle is same that of phenakistoscope. It is a cylindrical rotating instrument with

many frames of images printed on a paper strip kept over the inner circumference. The observer watches through vertical slits around the sides and view the moving images on the opposite side as the cylinder rotates. As it rotates the frames between the viewing slits moves in the opposite direction of the picture on the other side and serves as a micro shutter. It does not require the use of a mirror to view the illusion, and as it has cylindrical shape it can be viewed by many at a time.

Flip Book

John Barnes Linnet, introduced the first flip book in 1868 and named it as Kineograph (moving picture). It was a book which had a series of images, when flipped shows that the drawings are moving. It is the simplest way of making animation without a camera.

Praxinoscope

In Greek praxein means action and scope means watcher. Praxinoscope had got two variants namely

non-projective and projective. Non-projective praxinoscope is the successor to zoetrope invented in 1877 by a French science teacher, Charles-Emile Reynaud. The narrow slit in the zoetrope was replaced by an inner radius of mirrors, kept inside so that the reflections of the images seemed to be more or less stationary in position as the wheel is rotated. Non-projected praxinoscope gives images that are less distorted and brighter than the zoetrope gives. In 1889 Reynaud introduced an improvised version which could project pictures on a screen from a longer roll of images. This projected praxinoscope was used for the benefit of larger audience.

Stop Frame Animation

During late nineteenth century stop frame animation had got its lime light. Stop Frame Animation is a film making technique to make a physically manipulated object appears to move on its own, this is by using individual camera shots of a different movement. Putting these shots together results in an animation impact. There are many types of stop frame animation namely clay animation, sand animation, cut-out animation, object animation, puppet animation, graphic animation and so on. Even though it is a time consuming process it leaves an impact on learning in a positive way and enhance look and feel.

Clay Animation

Clay animation is one of the many forms of stop frame animation invented in the year 1897 in which each of animated piece is made of a malleable substance, usually plasticine a type of clay. In claymation (short for clay animation) each object is made of clay or pliable material usually surrounded with skeleton wire called an armature. An armature can be built to support the clay figure using wire, tin foil, Styrofoam balls and Popsicle sticks. The series of capture with malleable figures ensures the impact of animation.

Sand Animation

Sand animation, otherwise called as sand art, in which an artist forms a series of images with sand. At first an artist applies sand to a surface like glass and then forms images by drawing lines and figures in that sand with his hands. In this sand animation overhead projector or light box is used as an aid by the performer. Then the animator moves the sand around on a back lighted or front lighted piece of glass to create each frame and on sequential grab the effect of animation is bestowed over sand images.

Cut-Out Animation

Cut-out animation is one of the stop frame animation techniques using flat characters, props and background cut from materials such as paper, card, stiff fabric or even photographs. The characters are fragmented into smaller pieces and captured the pieces by giving small movements manually, at each step, to create the illusion of movement. The cut-outs may be of paper drawings, photographs or any 3D objects. The cut-out animation process is a tedious one as it needs manual intervention that is the animator has to adjust the pieces for every frame.

Object Animation

The animation created with the use of any non-drawn objects like toys, blocks, dolls, etc. that are not fully malleable, such as clay or wax and not formed to look like a living or non-living character.

Puppet Animation

The puppets or toys which are flexible to move their parts, so that they can be repositioned between frames to create the illusion of motion are used in this variant. When the frames are played in rapid sequence the puppets are getting life. From the ancient times puppets are used for story

telling in ceremonies and later it came to the form of animation.

Computer Animation

The animator uses software to draw models and objects. The animator can animate irrespective of physical laws like gravity, mass and force. Early digital computer animation may be the brain child of Bell Telephone laboratories during 1960's. Lawrence Livermore of National laboratory had also indulged in developing early digital computer animation. There are two types of computer animation 2D animation and 3D animation. During 1976 the concept of 3D animation caught up and development of Computer Generated Imagery (CGI) technologies had given life to 3D games and game engines.

2D Animation

The 2D animation images are created or edited using 2D bitmap graphics or 2D vector graphics. Analogue computer animation, power point animation and flash animation are some of the applications of 2D animation.

3D Animation

In 1972, Frederic Parker created the first 3D human face model. In 1973, Edwin Catmull one of the founders of Pixar Animation studio created digitized hands. 3D animation is digitally modelled and manipulated by an animator. 3D animation is carried out through step by step process.

As in any scientific venture 3D animation also requires lots of planning. A creative artist with unquenchable imagination prepares the digital space. The 3D animation software packages like Maya and 3Ds Max exploit the use of node system. Node system is interesting, flexible and robust at the same time it is challenging when it comes to execute command. The software keeps in mind every command that is given in a linear fashion and calculates how things would look like with

the first node and keeps in track and moves in to subsequent frames. First the digital artist creates image planes that will describe the exact objects in different axes and integrates to create the three dimensional model that is made up of wire frame structure. The Euclidean geometry model depicts X axis as horizontal, Y as vertical and Z as depth, that involves lot of mathematical equation and algorithms. In this stage in Maya the artist can view the wire frame structure by pressing 4 or he can get the other rendering options like smooth shaded, smooth shaded with hardware texturing and smooth shaded with lights.

After finalising the structural part of the model the surface is textured as per the need of the animation theme. The appropriate light arrangement is provided on the objects and rendering is the part that ensures improvisation every time.

Once the visuals are finalised the story board developed by the director guides the animation engineer to what extent the objects stay and move in the screen through timing schedule. The animator provides the commands to the objects to make required moments followed by rendering and editing. At last the voice over takes place with music or description addition and the 3D animation is finalised through analysis by the stake holders. Thus making 3D animation is the cyclic process that offers improvisation always.

BACKGROUND

Teaching of Science Through Animation

It is needless to underline the importance of Science in the digital era. The accumulation of new scientific inventions are taking place in one hand, the dynamic principles of curriculum always push forward the developments at the earliest to the curriculum on the other hand. And it is evident that many school teachers teach in schools what they studied in their college that stands testimony to the rapid developments that are taking place in the

ambit of science teaching. It is the paramount task before the science teacher to explain the increasingly abstract topics in a jammy academic year full of hectic activities. This situation warrants the resetting of the compass of work ethics for science teachers. In this pressure cooker situation the search for better instructional media that will ensure greater individualisation and better illustration becomes inevitable. The present generation kids are glued to television animation and keep spending more time in animated games even. It is not pathological but has become the symptom of normalcy in the society where both the parents are employed and children left with only virtual world. Many experimental studies in this area give some meaningful findings for the usage of animation to teach science. Some topics like skeletal structure, illustration of crystal lattices, molecular labelling of chemical kinetics, internal structure and function of many internal organs like eyes, kidneys, heart and so on can be better explained with animation and aid the learners to take it to their long term memory and better achievement.

Psycho-Pedagogy Behind Animation

The effective use of technology for optimum realisation of educational objectives always seems to be the task on the table for majority of educational researchers. The advances in cognitive psychology provide convincing theoretical backdrop to use multimedia and web based technologies to improve learner participation, enhance learning outcomes and to extend active retention with better memory traces. As per Mayer (1991) through multimedia learning learners indulge in three important cognitive activities like selecting, organising and integrating. By these activities the learners build connections between verbal based models and visual based models with enriched prompts and cues.

It is the assumption that animation provides separate systems for processing pictorial and verbal materials. In this dual channel assumption each channel has got limited amount of material that

can be processed at a time. Meaningful learning is ensured only when these mental connections between pictorial and verbal representations are complete. The alternate school of thought which highlights the cognitive overload is diminishing day by day. As per these theorists the learners intended cognitive processing exceeds the available cognitive capacity of the learners. This argument is losing its ground as more and more scientifically designed and pedagogically superior educational animations becoming runaway success.

Julie Bauer (2002) is of opinion that graphics have been used from the past to portray things that are inherently spatio-visual. Concepts that are metaphorically spatio-visual can be better explained with moving graphics than static graphics when it conforms to congruence principle of learning. For real time reorientation of time and space animation is the tool that stands taller in spatio-visual ambience. Multiple representation principle, contiguity principle, split attention principle, individual differences principle and coherence principle if applied judiciously in educational animation tastier will be the fruits of education.

Need and Significance of the Study

The classroom trend changes from manual to technological and therefore the conventional way of teaching is not enough for the children. Today the children need active participation in the classroom. They need their teachers to be a motivator, active participant etc., since the availability of many software make the teachers feel free and easy to design their own style. Even though it is the additional workload for the teachers the learning outcome or evaluation gives some satisfactory improvement (Sajid Musa 2015).

The main intension of animation class is not only in creating curiosity but also helps to sustain their interest and attain curricular objectives. The concepts which they learnt through animation withstand the retroactive inhibition of memory which makes their studies a productive one for their future aspects.

The animation class not only makes the children to learn, but it makes them to understand. It creates some positive attitude among the learners to pursue education with ease (Falode 2016). This study is the need of the hour to assess whether animation has got positive educational outcomes for teaching and learning communities.

The effectiveness of an educational animation largely depends on the soundness of its psychological constructs. Animation in education motivates the learner in an interesting way in which traditional method of "Chalk & Talk" is avoided and also minimises actual classroom demonstration & lecture. While using educational animations not only creativity & novelty is increased among learners monotony is also reduced. Animation creates liveliness in the classroom situation and prolongs retention, it keeps the learners attentive and thereby learners can easily understand the concepts of the subject easily when compared to traditional method of learning. Many of the complex ideas become easier while using animation and also matches the cognitive demands of a learning task. (Tversky et al. 2002)

Animation has the potential to attract the concentration of learners in their topics through visualization of content. It's an enjoyable and memorable one where animation leaves a lasting impression and form a stronger relationship, making them more likely to respond. Watching a video is easier than reading a lengthy document or book; it not only saves the time but also makes sure your message get across. Present both auditory and visual stimulus to the students, allowing easier cognitive tagging and encoding of information besides triggering the imagination of learners.

Limitations

The educational effectiveness of any visuals largely depends on how widely it is used by the instructor rather than how well learners learn when animation is used. So it lies with the instructor to maximize the utility of animated media to supplement the face to face instruction. Many a

times out of vested interest or technical inertia the instructor in developing countries are miles away to make up their mind to go for animation.

Mostly real life learning is lost in animation. Students are fostered with virtual ecology. The individual differences prevailing among the learners may not be effectively addressed with animations that are targeting generalised perspectives.

Review of Related Literature

Review of related literature provides innumerable studies in this area, for brevity a few studies are highlighted hereunder followed by Meta synthesis.

Angelos Konstantinidis and others (2013) introduced four Web 2.0 tools; Blogger, Strip Generator, Go! Animate, and Google Forms, that are free and easy to use, in an effort to motivate teachers with low technological skills in integrating them into their instruction practices. In their descriptive method they found that the aforementioned tools comprised the curriculum in a blended-learning professional development course for in-service teachers that attracted many favourable comments from the participants.

Lirong Xiao (2013) made a survey through inquiry forms about animation content in education and found that in animation field, although some software companies have developed their individual production toolboxes or platforms for animation content in education, there is lack of relevant research from the perspective of animation techniques.

Sederick C. Rice (2013) used interactive animations to enhance teaching, learning, and retention of respiration pathway concepts in face-to-face and online high school, undergraduate, and continuing education learning environments. The study found that the content used for the research supports the development of more inquiry-based classroom and distance-learning environments that can be facilitated by teachers/instructors, it also improves retention of important respiration subject content and problem-based learning skills for students.

Gokhan Aksoy (2012) analysed the impacts of animation technique on academic performance of students in the “Human and Environment” unit present in the Science and Technology course of the seventh grade in primary education with 58 students. The study revealed that animation technique is very effective when comparing with traditional teaching methods in terms of improving students’ achievement.

Waqur Un Nisha Faizi and others (2012) identified the main causes of increasing attention towards animation course in different institutions of Karachi through survey method. The researchers found that majority of the respondents had a view that animation course ready to meet the need and requirement of modern times. Some respondents opined that students of animation class lead a happy and prosperous life at the end of the course and animation course grooms the ability of decision making among students.

Animesh K. Mohapatra (2013) probed the extent of computer animations in teaching membrane transport to pre-service teacher trainees’ and the extent of understanding of concepts and functions in membrane transport. Many a times educators find it difficult to teach various membrane transport processes, as many of the resources are two dimensional whereas membrane transport is four dimensional in nature. Much research finding support that viewing the processes in three dimensions helps better learning, and animations are perhaps effective visualization tools for learners and help to retain for long-term. It was concluded that animations with movements can provide learners with explicit dynamic information that is either implicit or unavailable in static graphics. Therefore, it was recommended to use computer animation to transform students to active mode.

As it had been observed that this particular field of study has got immense potential and the available literature also has got spaces to fill with this study on “Science Animation and Students Attitude – An Analytical study” has been taken up.

METHODOLOGY

Assumption of the Study

Gaining of knowledge through learning is a day-to-day process which we experienced from our childhood. All the people don’t have an opportunity to engage in learning through schools or colleges throughout their life. Apart from the educational institution students learn a lot from their environment which are unorganized and perhaps unauthentic. The systematic method of constructing scientific and verified knowledge is received only from the schools, so one should be aware of what they learnt and it should be useful to their life. The purpose of education is to make a learner to be a learner for their life time that is they should not be filled with bookish content alone and they must know how to convert the content to their practical utility.

The engaged time of the institution must be better transformed into academic learning time. The relatively small portion of time is only going to create a large impact in the cognitive structure of an individual. The tools those are useful to make better memory traces with the learner can be complete only with animation.

Thus the researcher by this assumption made the following research questions.

1. Do animated lessons trigger the learners’ interest?
2. Does animation find useful place in curriculum?
3. Do animated lessons increase the span of attention?
4. Does animation make learning a joyous one?
5. Do animated lessons ensure better understanding of the content?
6. Can students achieve better with animated lessons?

Objectives of the Study

The following are the objectives

1. To measure the span of attention of the students studying through animated lessons.
2. To find out the curiosity in the learners towards animation lessons.
3. To analyse the difference in achievement between conventional class and class with animated lessons.
4. To evaluate the level of understanding of students attending the class with animated lessons.
5. To evaluate the relationship between achievement and attitude of students attending the class with animated lessons.
6. To find out the relationship between the attitude and its sub variables towards animation.
7. To evaluate the effectiveness of the class with animated lessons in science subject.

Hypotheses of the Study

The following hypotheses were formulated based on the objectives of the study.

1. There is no significant difference between control and experimental group in their pre-test achievement.
2. There is no significant difference between control and experimental group in their post-test achievement.
3. There is no significant correlation between experimental group post test achievement and students attitude towards animation.
4. There is no significant correlation between experimental group post test achievement and the sub variables of attitudes towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation.
5. There is no significant correlation between experimental group students' attitude and the sub variables of attitude towards animation

like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation.

6. There is no significant cross correlation between sub variables of attitude towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation.

Research Design

To study the effectiveness of teaching through animation, the pre-test, treatment, post-test equivalent group experimental design was adopted in the study. A sample of 43 students for each control and experimental group were selected by purposive random sampling based on their academic term achievement. The equivalence of mean achievement was taken into consideration to finalize the sample of both groups. The following tools were used in the study.

Tool 1: Achievement test in science constructed & validated by the investigators.

Tool 2: Scale of attitude towards animation lessons constructed & validated by the investigators.

Research Procedure

The population may be school students studying science as one among their subjects, the representative sample was selected from a private school in Kumbakonam of Thanjavur District for both control & experimental groups. The students studying in eighth standard (280) were screened through their achievement in term test. Among the 280 students the investigator adopted purposive sampling technique to select the students who fall in the average category (50% - 60%) that accounted 86 students based on their term test marks. 86 students were randomized and split into 43 each to form the control and experimental groups for the study.

The pre test was administered to both the experimental and control groups and data were

collected to assess the achievement of the students. The topics were selected from science textbook and were taught to the control group with conventional method. For the experimental group the same topics were taught with animated lessons for 30 days. The animated lessons are mostly 2D and 3D animations those are freely available to the users. Both control and experimental group were instructed by the same investigator. For the execution of animated science lesson the investigators had selected animated videos from selected websites that provide free feed. After the treatment period the post test was administered for the sample and data were collected for achievement test. Scale of attitude towards animation lessons was administered on experimental group after post test to assess their attitude about the treatment.

DESCRIPTION OF RESEARCH TOOLS

Construction of Achievement Test

The achievement test was constructed by the investigators from the topics which they planned to teach the students using animation. Investigators reviewed the Tamilnadu State Board Textbook for standard eight and finalized the topic pertaining to second term science and settled with two topics namely skeletal system and atomic structure. The syllabi and their finalization were carried out with the help of research supervisor, four experienced teacher educator and Principal of the school, Module 1 consisting animated video of human body and its movements, joints and types of joints, skeleton and movement of animals. Like wise module 2 consisting law of conservation of mass, law of definite proportion, Dalton's atomic theory, discovery of electron, properties of cathode rays, discovery of protons and Thomson's atomic model.

Achievement Test

Standardization

The test items constructed were subjected to jury's opinion consisting of research supervisor, principal of the school and four experienced teacher educators. To establish the reliability of the test, the investigator adopted split-half method. The reliability of the whole test is found to be 0.86 significant at 0.01 levels. Hence it is concluded that the test is highly reliable. To establish the validity of the test the investigator attempted to find out the correlation co-efficient between the achievement scores in the test and scores they got in their term test by product moment correlation co-efficient method by taking 25 percentage of the total sample of 86 students. The correlation co-efficient is found to be 0.831 significant at 0.01 level. Hence it is concluded that the test has high validity. The content validity of the test was ensured by the panel that acts as jury. The answer books of the students for achievement in science were scored by giving one mark each for a right response of the objective type question, thus a range of 0-30 marks can be secured by the students.

Scale of Attitude Towards Animation Lessons

Attitude may be considered as the state of mind or feeling about anything or anybody. It is essential to estimate the attitude of the learners towards animation lessons and what really matters for them to have animation as the preferred mode of educational delivery. So the investigators would like to know the attitude of the students present in the experimental group towards animation lessons.

The investigators after having meticulous analysis and critical review with various stakeholders had extracted five important dimensions that compose the attitude of the students towards animation lessons as following

1. Narration
2. Visual transformation
3. Interest and attention
4. Easy and rapid understanding
5. Participatory evaluation

As much as 78 questions were developed in these dimensions. These questions were subjected to item analysis and expert regulations. The final version rested with 30 questions spread across all dimensions; the significance of each dimension is given below.

Narration

Narration is the use of a selected methodology or process of giving a written or spoken commentary to unfold a story to an audience. Narration embraces a set of approaches through which the author of the story presents it. Narrative mode includes Narrative point of view: The perspective through which a story is communicated and Narrative voice: The format through which a story is communicated.

In animated lessons the narration or the script board spells success to a greater extent. By narration the investigators mean the way of unfolding the scientific concepts by employing the technological pedagogical principles of learning and also child friendly elements like animated characters that may explain the lessons as video jockey with some sense of humour.

Visual Transformation

The visual elements that are rich in details and better in dimension may offer a meaningful understanding of the point of discussion. By visual transformation the investigators mean the change of frames that may offer more concrete idea about abstract concepts by means of taking the learners to the quint essential part of the topic.

Interest and Attention

Interest may be defined as the feeling one may have to know or to learn more about somebody or something. It may also be defined as an activity or a subject that one may enjoy and spend the free time in doing or studying it.

Attention is the act of carefully listening or thinking about something. By interest and attention the researchers mean a connection of the learner with animated lessons which affects his attitude towards it especially while he receives immense benefit and urge to attend the classes.

Easy and Rapid Understanding

The knowledge that someone has about a particular situation or subject may be termed as understanding. To gain that knowledge in a given topic if the learner is going to take less cognitive effort that ensures easy understanding. If the time that is going to be consumed is less by the learner to understand that may be considered as rapid understanding.

Through this dimension the researchers would like to seek whether animation lessons ensure easy and rapid understanding from the learner's perspectives.

Participatory Evaluation

Participatory evaluation is the partnership approach to evaluation in which the stakeholders actively engage in developing the evaluation and all phases of its implementation. The stakeholders are instructors, learners, decision makers and any other beneficiaries. The process includes identifying relevant questions, planning the evaluation design, selecting appropriate measures for collecting and analysing data (Ann zukoski and Mia Luluquisen).

Table 1.

Group	Sample	Mean	Std. Deviation	t	P value
Post-test (control group)	43	9.419	3.905	21.445	0.000
Post-test (experimental group)	43	25.326	3.037		

In this dimension the researcher would like to estimate the readiness of the learners to voluntarily ensure the progress by answering formative questions available in the particular topic with innate enthusiasm and self regulating their zeal to answer.

Statistical Techniques

Mean, Standard deviation, 't' test, Correlation, Regression, Effect size, Cohen's d and Gain score analysis are the statistical techniques that were employed for data analysis.

ANALYSIS AND INTERPRETATION OF DATA

Testing the Significance of Difference Between the Mean Scores of Pre-Test

The table value of 't' for the degree of freedom with 0.01 level of significance is 2.64, whereas

the calculated 't' value is 1.699. This makes it obligatory to accept the null hypothesis and concluded that there is no significant difference between the experimental group and control group students in their pre test achievement in science.

Testing the Significance of Difference Between the Mean Scores of Post-Test

The significance of difference between the mean of control group and experimental group of eighth standard students in their post-test achievement in science is shown in Table 1.

The calculated value of 't' 21.445 is significant at 0.01 level. This makes it mandatory to reject the null hypothesis and concluded that there is significant difference between the experimental group and control group students in their achievement in science in which the experimental group has got higher scores.

Figure 2.

Effect Size Analysis

Effect size analysis was carried out using pooled standard deviation to find out the relative effectiveness of the animated science lessons over the conventional method. The instructional objectives were same for the pre-test and post-test. The effect size for post test achievement is 0.915 that is large effect. Likewise the value of Cohen's d for the comparison of control and experimental group post test achievement in science is 4.543. These findings again prove the fact that students studied through animated lessons have fared better and the treatment is very effective over conventional method for the chosen topics. The average attention span observed by the investigator for experimental group was thirty five out of forty five minutes where as for the control group it was only twenty one minutes.

Gain Score Analysis

The gain score analysis of control and experimental post test achievement in Science revealed that the experimental group has got mean achievement of 25.33 in contrast to 9.42 of control group that is 169% is the gain score of the experimental group

post-test achievement. This substantiates that the treatment with animated lessons seems to be very effective over conventional method of teaching.

Correlation Analysis

There is significant positive correlation between experimental group post test achievement and students attitude towards animation with 0.01 level of significance. This gives way to reject the null hypothesis and concluded that achievement in Science and attitude towards animation lessons with experimental group have meaningful correlation that may be attributed to animation lessons.

Testing the correlation between experimental group post test achievement and the sub variables of attitudes towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation

The correlation between experimental group post test achievement and the sub variables of attitudes towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation is shown in Table 2.

Table 2.

Variables	N	r
Experimental group post-test vs. Narration	43	0.522**
Experimental group post-test vs. Visual Transformation	43	0.530**
Experimental group post-test vs. Interest and Attention	43	0.522**
Experimental group post-test vs. Easy and Rapid understanding	43	-0.268**
Experimental group post-test vs. Participatory Evaluation	43	0.425**

** Significant at 0.01 level

Figure 3.

There is significant positive correlation between experimental group post test achievement and the sub variables of attitudes towards animation like narration, visual transformation, interest & attention and Participatory evaluation except easy and rapid understanding and makes it mandatory to reject the null hypothesis except for the sub variable Easy and Rapid Understanding.

Testing the correlation between experimental group students' attitude and the sub variables of attitude towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation

There is significant positive correlation between experimental group students' attitude and the sub variables of attitude towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation except Easy and Rapid Understanding and thereby it is obligatory to reject the null hypothesis.

Testing the cross correlation between sub variables of attitude towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation

The cross correlation between sub variables of attitude towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory evaluation is shown in the Table 4.

There is significant positive cross correlation between sub variables of attitude towards animation like narration, visual transformation, interest & attention, easy and rapid understanding and Participatory Evaluation. This gives way to reject the above said null hypothesis for all the sub variables except Easy and Rapid Understanding.

Regression Analysis

The scores of students' attitude towards animation and its sub variables with respect to achievement

Table 3.

	Narration	Visual Transformation	Interest & Attention	Easy & Rapid Understanding	Participatory Evaluation
Attitude	0.733**	0.949**	0.922**	-0.764**	0.725**

Table 4.

Sub variables	Narration	Visual Transformation	Interest & Attention	Easy & Rapid Understanding	Participation Evaluation
Narration	1	0.849**	0.897**	-0.615**	0.425**
Visual Transformation	0.849**	1	0.988**	-0.856**	0.573**
Interest & Attention	0.897**	0.988**	1	-0.838**	0.530**
Easy & Rapid Understanding	-0.615**	-0.856**	-0.838**	1	-0.519**
Participation Evaluation	0.425**	0.573**	0.573**	-0.519**	1

in science are subjected to regression analysis that yielded the following interpretation.

Predictors: (Constant)- Post Test Achievement of Experimental Group in Science

The method used in this analysis is enter method. The dependent variable is achievement in science and the variables entered are attitude towards animation and its sub variables. The adjusted R square value is 0.364. This indicates that the independent variable in this model account for 36.4% variance in dependent variable that is achievement in science. Both the constant and few of the sub variables has got significance level of 0.01 – 0.05. The β coefficient is significant at 0.05 level. This indicates that the achievement in science, attitude towards animation and its sub variables are positively related except the sub variable easy and rapid understanding.

Findings

1. It is found that there is significant difference between the experimental group and control group students in their achievement in science in which the experimental group that

learnt with animated lessons has got higher scores.

2. It is found that there is significant positive correlation between experimental group post test achievement and student's attitude towards animated lessons which proves that instruction with animated lessons seems instrumental in building a positive attitude towards animation lessons among the majority of the students.
3. It is found that there is significant positive correlation between experimental group post test achievement and the sub variables of attitudes towards animation like narration, visual transformation, interest & attention and Participatory evaluation except easy and rapid understanding. It gives an inference that people who have positive attitude towards narration, visual transformation, interest & attention and Participatory evaluation that may be created out of animated classes had scored better in their achievement test in science.
4. It is found that there is significant positive correlation between experimental group students' attitude and the sub variables of attitude towards animation like narration, visual transformation, interest & atten-

tion, easy and rapid understanding and Participatory evaluation except Easy and Rapid Understanding that gives an insight that most of the sub variables has got right orientation with attitude towards animation and perhaps Easy and Rapid understanding had not been preferred to the extent it had been preferred that the top scorers whereas it seems the poor scorers has preferred this dimension as essential.

5. It is found that there is significant positive cross correlation between sub variables of attitude towards animation like narration, visual transformation, interest & attention and Participatory evaluation except easy and rapid understanding.

Educational Implications of the Study

This study reveals that science instruction with animated lessons is very effective in improving the achievement of students in school science. The overall outcome of the study highlights the effectiveness of teaching with animated lessons with large effect size and gain score in achievement of Science. The attitude of the students towards animation classes is very positive. This study implies that teaching with animated lessons will definitely enhance the outcome of teaching learning process in the following ways,

1. Animated lessons make the learners to be attentive and focused.
2. Animated media offers in-depth details to make the students thoroughly understand the abstract elements present in a particular topic.
3. Visual transformation and Narrative paradigms that are employed in animated lessons seems to be psycho pedagogical in nature to sustain the interest of the learners and to complete the syllabus in time.
4. The effort required by teacher and learner alike can be minimised with animated classes.

5. As animated lessons are self explanatory and informational through multiple media, the impact on memory traces would be long lasting.

FURTHER RESEARCH DIRECTIONS

This study entitled “Science Animation and Students Attitude-An Analytical Study” is an investigation at standard Eighth level. It is suggested that further studies may be conducted in the following areas,

1. It is suggested that teaching through animation is evaluated in other school subjects like Mathematics, Social studies, Language I and II etc.
2. It is suggested that the same study is carried out in all standards of different boards.
3. It is suggested that the same study is carried out in higher education and professional education courses.
4. It is suggested that the influence of other variables than those studied now can also be investigated.
5. It is suggested that efforts should be taken to develop animated lesson for more topics and evaluate their effectiveness.

CONCLUSION

Through animated lessons science can be taught effectively. More and more new information with the support of modern electronic media can be passed to the learners easily. In the information era ocean of information cannot replace the teacher and his personal influence in the mind of the learner. In this method the teacher is having face to face interaction and gives guidance about the veracity of the content to ensure the right learning to take place through self motivated learners. Though the groups in the study are homogenous, the differences in mean score and standard deviation will stand testimony to the fact that, teaching

science through animated lessons is superior to conventional method of teaching. There seems to be no doubt that auto instructional strategies are supplementary as well as main process of learning. Teaching is replaced by learning, ultimately leading to self learning thus teaching science subject through animation fill the gaps of the conventional teaching learning process.

KEY TERMS AND DEFINITIONS

E

Animation: Latin word ‘animatio’ that means the condition of being alive or giving life.

Attitude: The state of mind about anything or anybody.

Computer Animation: The images or objects that are created using computer software subjected to animation.

Effectiveness of Animation: Remarkable achievement of learners by the impact of animation.

History of Animation: The growth and development took place in the field of animation.

Psycho-Pedagogy: Educating the learners through the principles of psychology.

Science Animation: Animation clippings that are used to explain science concepts.

Visual Transformation: Change of visual frames in any video.

Three Cases of Unconventional Educational Uses of Digital Storytelling

Emmanuel Fokides

University of the Aegean, Greece

INTRODUCTION

The narration is the art of using words and actions for the representation of the elements of a story in such a way that the listener's imagination is stimulated (Genette, 1998). More simply put, it is the art of telling a story to an audience, in order to convey important messages. Due to the technological developments, storytelling has become digital; the oral or written story is enhanced by using multimedia and hypermedia elements (Lathem, 2005). Narrations, either digital or conventional, are useful educational tools. Since narrations cause the keen interest of students, this helps them to easily consolidate and assimilate information (Coventry, 2008). They increase the oral and written skills, strengthen critical thinking and the ability to analyze and synthesize information (Ohler, 2006). When students create their own digital stories (individually or as a group), they learn to conduct research on a topic, to ask questions, to organize ideas, to express their views and to make meaningful narratives (Robin, 2006).

There is an extensive literature regarding the educational benefits when using digital storytelling (e.g., Coventry, 2008; Ohler, 2006; Robin, 2008). Disproportionally fewer studies have been conducted examining the potential of this tool in areas where the settings are not strictly instructional or the main objective is not some form of knowledge acquisition. The present study is an attempt to fill that gap, by embracing the standpoint that digital storytelling is a good method for documenting personal experiences, that it can be a form of narrative therapy and that it can help students to discover parts of their

personality (Sawyer & Willis, 2011). Three case studies are presented where digital storytelling was used in a non-mainstream, unconventional way. In all, knowledge acquisition was irrelevant or an insignificant factor; instead, the emphasis was on broader issues that students, as well as teachers, face at school.

BACKGROUND

Focusing on problems that students and teachers face at school, which are not directly related to knowledge acquisition, but affect how the school functions and/or the emotional well-being of students, three areas were of interest: the poor school integration of immigrant students, young students' adjustment to school, and bullying.

In Greece, 10.35% of the total students' population are immigrants (Hellenic Statistical Authority, 2011). Insufficient knowledge of the Greek language and, consequently, low performance in language lessons is a major problem (Retali, 2013). There is also a more important difficulty; that of poor school and/or social integration. Schools could play an important role, but the Greek educational system is not capable of assimilating immigrant students well (Skourtou, Vratsalis, & Govaris, 2004). Therefore, there is a need to help them overcome their adaptation problems.

Coming to primary school for the very first time marks the beginning of a transitional period to children's lives. Rules and routines are different from those they were accustomed in the kindergarten and their status and identity might be affected (Fabian, 2007). Problems may arise

that have short and long-term educational and/or psychological implications (Dockett & Perry, 2009). Behavioral problems are also common (Brooker, 2008). Consequently, finding ways that allow a smooth and quick transition to the school's environment are quite important.

Bullying is a phenomenon that is becoming more and more frequent in Greece's schools. It greatly affects students' psycho-emotional development, their school performance (Manesis & Lambropoulou, 2014) and may lead to serious psychological trauma and dysfunctional social behavior (Galanaki & Vogiatzoglou, 2015). In hypothetical situations children easily express their intentions to help the victim or to report the incident (Rigby & Johnson, 2006), but in reality, only a small percentage actually acts (Salmivalli, Lagerspetz, Bjorkqvist, Osterman, & Kaukiainen, 1996). Studies, in Greece, examining interventions where students actively participated and were not just passive receivers of information are sparse (e.g., Kyriazis & Zacharias, 2015). Thus, there is a need to inform them in a more comprehensive way.

The coming sections present how these issues were dealt using digital storytelling.

MAIN FOCUS OF THE ARTICLE

Case 1: School Integration of an Immigrant Student

In order to help a sixth-grade female immigrant student, having significant adaptation problems, a short project was planned and carried out, at a primary school in Rhodes, Greece, from late October 2014, till mid-March 2015. Twenty students (including the subject) were involved. The main idea of the project was to ask her to develop and present to her classmates an autobiographical digital story, illustrating her thoughts and feelings from her transition from one country to another.

She was selected as the study's subject because: (a) she recently came to Greece from the Domini-

can Republic. There were no other immigrants from that country; therefore, no one could help her and her family during their transitional period, (b) she did not socialize with the other students, whose attitudes toward her were "indifferent", (c) she should be attending high-school, but because of her poor school performance she had to repeat the primary school's last grade, and (d) her adaptation problems had worsened because of (c). From the above, it can be argued that she reflected characteristics and problems arising from the fact that she was an immigrant, therefore she constituted a critical case (Flyvbjerg, 2006). Data were gathered from multiple sources; interviews, direct observations, drawings, and the subject's digital story.

The interviews with the subject's teacher were about her difficulties in social interaction with her classmates. The interviews with the students focused on how they view and interact with her. The interviews with the subject focused on the difficulties she was facing and the level of social interaction with her classmates. The in-classroom observations were focused on her behavior and the attitudes of the other students toward her.

The development of the story lasted for a month, with a total of nine one-to-two hour sessions. It consisted of three parts: (a) "Before leaving" (seven scenes), where her thoughts, feelings, and conversations with relatives and friends were depicted, (b) "The journey" (two scenes) where her first impressions of her new home were illustrated, and (c) "In Rhodes" (two scenes) where her situation at school was portrayed. Her favorite song when she was living in her homeland accompanied the first part, while in the other two parts she used her favorite Greek song. Even though all dialogues and thoughts were written in Greek, they were "spoken" in Spanish, using her own voice. It has to be noted that during the development of the subject's story, the researcher did not intervene in any way. This was done because guidance regarding the structure or the content of the digital story, might have resulted in the alteration of the results.

Her detachment and loneliness were strongly portrayed at the third part of the story (e.g., all students are playing, but she sits alone and no one is talking to her), in contrast to the first, which is full of dialogues with relatives and friends. This contrast, reveals the extent of the lack of interaction and communication with others and her strong feelings of isolation and solitude. Also, the story was -in some sense- bilingual. Texts were in Greek; the narration was in Spanish. This fact, together with the Spanish song in the story's first part, had an impact on students. Photos, language, and music, combined together, helped them in having a better understanding of the subject's culture, as they stated in their interviews.

In their initial interviews, the majority of students (16) expressed the view that they have no dissimilarities with foreigners, with the exception of language. However, their focus was on the language and communication problems and not on the immigrants' feelings. After the presentation of the story, students stated that they gained a better understanding of the immigrants' problems (17 cases). There was also a shift in their focus; from communication problems to the immigrants' feelings of loneliness and isolation.

From the analysis of the initial subject's interview, the strong attachment to her country became clear. Loneliness, unhappiness, anxiety and fear about whether she will be accepted, were her strongest feelings. Significant changes were noted after the intervention; she felt more accepted and, finally, she had started socializing with other students and she was quite happy about it.

The researcher's observations and the teacher's interview also confirmed the positive change in the subject's behavior and socialization. A positive change to the other students' behavior was also observed, the most important being that students acted. The communication barrier was lifted by both sides. Not only the subject was more open in joining groups of students, but also, they were more open in asking her to join them, in various activities.

Case 2: School Adjustment

In order to facilitate students understanding of the functions and rules of school and to change the attitudes and behaviors of those having adjustment problems, a short project was developed, involving the use of a technique to foster positive behaviors, combined with digital storytelling. A total of a hundred and five first-grade students participated, from five primary schools in Athens, Greece. The project lasted from mid-September (schools in Greece start in mid-September), until late October 2015.

Behavioral modeling and, in specific, mimicking was utilized (Akers, 1977). In mimicking, one observes a model that expresses the desired behavior and, subsequently, he/she adopts it (Rogers, 2003). If ready-made stories were used, it would be like lecturing students. Instead, students were asked to develop their own. Since they were not yet able to read and write (at least efficiently), they acted as the "brains" and teachers acted as their "hands". The digital stories' developing software was projected using the classes' video projectors, students saw what available choices they had, collectively determined what to do, and "commanded their teachers to execute their will. In reality, teachers indirectly guided students to certain key points, by constantly asking questions about the conditions and behavioral problems that prevail in their classrooms. The outline of the stories was "A day at school" and the idea was to develop two-part digital stories. On the first, "wrong" students' behavior and dysfunctional classes were depicted. On the second, all problems were resolved and the "ideal" students' behavior was portrayed. This stage of the project lasted for two weeks (seven two-hour sessions).

Multiple sources of evidence were to be used as suggested by Yin (1994) and Paton (1990); pre-, during, and post-stage observations together with pre- and post-stage interviews with teachers and students were used for data collection purposes. This is a form of triangulation, which allows the

verification of interviews while interviews allow the researcher to explore the internal aspects of the underlying behavior (Patton, 1990). The focus of the observations was incidents of poor school adjustment and behavioral problems. The teachers and the students presenting significant adjustment problems were asked about the observed episodes, in order to understand and clarify their intentions and/or interpretations of the events.

During the observations prior to the development of the stories, it was noted that 14 students (9 boys and 5 girls) had considerable adjustment and behavioral problems and became the study's focus students. Each repeatedly exhibited the following categories of problems: (a) lack of self-restraint/discipline, (b) lack of interest or denial of participation in the lessons or in the school activities, and (c) denial to follow rules. Also, 24 students presented some of the above problems, but these were sporadic. The rest of them did not present any problems, or they were negligible. A noteworthy finding of the focus students interviews was that, though they could understand that their behavior was wrong, they could not make the connection between wrong behavior and its consequences, except for the ones that were related to them.

Students found the notion that teachers were their "hands" and that they were the "brains" very interesting and fun, and they were constantly asking to add more scenes to the stories. In the first part of the stories they effortlessly illustrated the characters' wrong behavior at school. What was not expected, but actually happened, was students to easily portray the ideal conditions. All the basic functions and rules that govern school seemed to be understood and the same applied to what was considered appropriate behavior.

During post-stages' observations, a sharp decrease in all problems was noted, but they were not totally eliminated. The results were especially interesting in the focus group, in which the majority of the focus students (12 out of 14) exhibited only minor behavioral issues. Also, teachers and students alike, quite often, referred to the digital

stories during in-classroom conversations and/or arguments. During post-stage interviews, the matter of focus students not being able to make the connection between wrong behavior and its consequences to others was reinstated, to evaluate if any changes had occurred. Indeed, 8 students gave answers that clearly indicated that they understood that there were broader implications.

Case 3: Dealing with Bullying

Since incidents of bullying are becoming more frequent in Greece's schools, an intervention was planned and carried out in the fourth grade of a primary school in Rhodes, Greece, from late October 2015, till late November 2015 (ten two-hour sessions). Twenty-four students were involved. The goal was to inform students about bullying. The main idea was students to work in groups of four, develop bullying stories, present and discuss them to the classroom, and collectively develop one final story. The researcher offered no help or guidance and did not intervene in the process, with one exception. In the final story, he suggested three alternative endings; the victim remained silent and continued to be tormented by the bully, the victim reacted, but failed because the bully was overwhelmingly powerful, and the victim became a bully himself, harassing younger students. Following the presentation of the final story, students were asked to write a short essay, presenting their thoughts and feelings for these endings and the way they would have reacted. Research data were obtained by analyzing the digital stories and the short essays using the iterative coding process (Creswell, 2002) to identify the categories, themes, and patterns that emerged from the data. All stories were viewed once, by two individuals, to identify the main ideas. Then, they were re-viewed in more detail and the ideas were labeled with codes. This process was repeated two more times to reduce overlap and redundancy of the codes until a small set of sub-themes were identified.

Physical together with verbal bullying were the main themes in all scenarios. All stories although simplistic, accurately illustrated what bullying is: the repeatedness of the incidents, the use of violence and bad language, the abuser's overwhelming power, the victim's reluctance to report the events. Emotions, like fear, depression, loneliness, and embarrassment, were also accurately presented. Bullies in all cases were boys. In all but two cases, the victim was a boy. Bystanders were included, but in most cases, there were no dialogues or thoughts accompanying these characters, so it is impossible to know which type of bystanders were portrayed. On a story, an observer helped the victim to beat the bully. The rest of the stories ended with the victim talking to an adult (two to a teacher, two to the victim's mother, one to the headmaster).

The three alternative endings of the final story were, in essence, wrong. Students' essays were evaluated on the basis of the reasoning for rejecting them and the reasoning for selecting their own "right" course of action. The negative emotions one has when being bullied, were enough for rejecting the first two of the alternative endings. The reason for rejecting the third ending was almost totally in line with the phrase: "We do not treat others in the same way they (wrongly) treat us". There were six cases (two boys and four girls) in which students stated that they would talk to an adult only if the bullying situation becomes intolerable, while in the rest, students stated that they would react immediately. The negative emotions of being bullied were once again the reason for seeking help if they were the victims of bullying. Finally, in all cases, talking to a parent, a teacher, the school's headmaster, to a friend or a combination of the above, were considered the "right" reaction if students were bullied or witnesses to bullying.

SOLUTIONS AND RECOMMENDATIONS

Setting aside the satisfactory results that all had, the cases presented in the previous sections share important common features. In all, digital storytelling was used in ways that deviate from its mainstream uses, that is in a strictly instructional setting, for simply telling a story, or for acquiring literacy skills. Taking advantage of storytelling's compatibility with young students' mentality (Robin, 2008), they explored alternative uses that all of them tried to resolve issues that students, as well as teachers, often face at school. Indeed, bullying, immigrants' integration problems and problems during the first days at school, are not rare and dealing with them can be quite difficult.

The rationale behind the three cases was based on two concepts. The first was that students' active participation is fundamental. Although a researcher, and/or a teacher was present, their role was limited; offering technical assistance when and if needed, not intervening at all, or covertly guiding. Social constructivism provided the theoretical foundation. By adopting the Vygotskian perspective, teachers were the ones who -indirectly- guided and supported students (Niesel & Griebel, 2007). By adopting the Piagetian perspective, students collaborated, negotiated, and came to a common consensus on how to develop their stories (Smith, 2012). By avoiding lecturing and direct manipulation, students' stories were not the result of someone imposing his/her thoughts and views on them. Instead, students were free to:

- Visualize their thoughts when developing the stories (Regan, 2008).
- Use, as raw material, pieces of previous knowledge and experiences they might have had.

- Construct their own understanding regarding important issues and socially negotiate them (Ertmer & Newby 2013).
- Embed their assumptions in real-world situations and determine by themselves the “right” course of actions.
- Become communicants of someone else’s thoughts, feelings, and problems (by viewing the digital stories) (Cane, 2010).

As a result, they formed a more comprehensive understanding regarding the issues that were discussed in the digital stories (Lenette, Cox, & Brough, 2013). Rules, instructions, good practices, behavioral patterns, and someone else’s emotions, require being deeply understood, before being accepted, applied, or become one’s own viewpoint.

The study’s second notion was that digital storytelling can be a form of a narrative therapy by helping students to discover parts of their personality (Sawyer & Willis, 2011). The power of stories as therapeutic means has been recognized by psychotherapy decades ago (White and Epston, 1990) The above was considered and utilized in the case of the immigrant student. Reflection on her problems, during the development of her story, and externalizing them during the presentation of the story, held the key to overcoming her problems (Rosenthal, 2003). Reflection and discussion of an issue were also key elements in the other two cases. Literature suggests that, when it comes to digital narrations, stories have to be told directly and unfiltered in order to act as a narrative therapy but also to start a dialogue among students (Harvey & Robinson, 2012). In turn, the discussion of a narrative promotes mutual understanding between students (Caine, 2010). The digital stories offered the basis upon which the process of documenting their experiences, reflecting upon them, and discussing them, was build and facilitated.

One has to be reminded that the researchers (or the teachers) avoided intervening, for purely research reasons; for not altering the results or for letting the students work by themselves. Contrary to that, in real-life situations, the teachers would

not be restricted. Taking advantage of the close affiliation between a teacher and his students, which is fundamental (Hamre & Pianta, 2006), results of such interventions are expected to be even better. That is because students will feel more comfortable in expressing themselves and the teachers, by knowing the background of each student, will be able to guide them more efficiently.

Considering all the above, it can be concluded that digital storytelling offered a simple, yet effective, solution to issues that are otherwise difficult to deal with. This solution can be summarized in just three steps: (a) ask students to develop digital stories on an important issue, (b) let them free to reflect upon that issue while developing their stories, and (c) discuss with them the issue while the stories are presented.

FUTURE RESEARCH DIRECTIONS

The main limitation in all the cases was the small sample size. Also, they were all conducted in Greece. Therefore, their results cannot be easily generalized. Further studies are needed with larger sample sizes and from different educational systems, in order to identify differences or similarities to the findings of the present cases and to obtain more reliable results. In addition, since the duration in all cases was short, longer-term projects can be tested, examining and comparing their results to short-term projects.

It would also be interesting to conduct research using conventional, instead of digital storytelling and compare the results. By doing so, it would be possible to determine if the results can be attributed to the medium used and/or to the methods.

Finally, one has to keep in mind that bullying troubles students of all ages, immigrant students face problems regardless of the level of education they study, and the transition from one level of education to another is always a sensitive period to a young student’s life. Therefore, virtually students of all ages can become target-groups of studies similar to the ones described in the previous sections.

CONCLUSION

In all the cases that were presented, the problems that were studied were dealt efficiently. Furthermore, all projects were short in duration and can be easily applied, without altering the school's timetable. Though it is certain that long term interventions yield good results, time is a crucial factor. Short term innovative interventions are needed because results can be produced right away and problems can be dealt on the spot. In all cases, whatever results were attained, were achieved fast, probably easing the way to follow up, longer term interventions. Also, no specialized equipment was needed and software similar to the one that was used is freely available.

In addition, the simplicity of the cases' design allows similar interventions to be easily applied to kindergarten, as well as to older students. Thus, teachers, as well as policy makers, can consider using their findings when designing similar or more well-organized, long-term interventions.

In conclusion, although the small sample size in all cases constitutes a considerable limitation, nonetheless, results point toward one direction; digital storytelling is a flexible and powerful instrument, an all-in-one tool, that can be used in many and diverse situations, educational or non-educational.

KEY TERMS AND DEFINITIONS

Bullying: The repeated use of violence (verbal or physical) and/or threats, for abusing, intimidating, or dominating others.

Constructivism: A learning theory which argues that humans generate knowledge and meaning from their experiences. Although not a specific pedagogy, is the underlying theme of many education reform movements.

Digital Storytelling: A digital form of a story that combines a conventional story (oral or written) and multimedia and/or hypermedia elements.

Mimicking: The observation of a model that expresses the desired behavior and, subsequently, adopting it.

Narrative Therapy: A form of psychotherapy in which an individual, together with the therapist, co-authors a narrative about himself/herself. Through this process, the values, skills and knowledge one has are identified, so as to effectively confront whatever problems he/she faces.

School Adjustment: The process of adapting to the role of being a student and to various aspects of the school environment.

Social Integration: The process in which all members of the society are engaged in a dialogue to achieve and maintain peaceful social relations. It does not imply or suggest forced assimilation.

3D Printing Applications in STEM Education

Norman Gwangwava

Botswana International University of Science and Technology, Botswana

Catherine Hlahla

National University of Science and Technology, Zimbabwe

INTRODUCTION

The chapter focuses on the design of educational toys for early school aged children, based on their anthropometric measurements. It also covers case study applications of 3D printing in engineering design undergraduate studies. Research on existing educational toys and different child development stages was carried out. Concepts were generated from the collected data and the best concepts selected through ranking methods. Dimensioning of the selected concepts was based on the collected anthropometry data. STL files were used to manufacture the chosen concepts by means of 3D printing.

Children are active learners who use the physical environment in a direct, hands-on manner to develop different skills. Toy experts believe that educational toys play a large role in the development of children. They stimulate play, language and reading skills and help children achieve milestones in both gross and fine motor skills. The implementation of ergonomics and the consideration of children's anthropometry dimensions in the design of toys play an important role in ensuring safety and injury risk reduction of children during play.

The National University of Science and Technology (NUST) is exploring 3D printing technology in the lecture room for its BEng program; ready-to-use 3D printed gardening implements, Mass-Customization of Office Mini-Storage Products from 3D Printing and other research

projects. 3D printing enables students in science, technology, engineering and mathematics (STEM) to visualize concepts.

BACKGROUND

Many of the children toys in the global market are imported from other countries, specifically China. The designers of these toys aim at achieving as good anthropometric match for as many potential customers in their country as possible. Thus the toys are custom designed to suit body dimensions of the children in that particular country yet the same toys are being exported and used by children across the world. Accidents and musculoskeletal health problems may occur due to incorrect product dimensions and sizes that do not meet the children's dimensional requirements.

Anthropometric data for children reflect general health status, dietary adequacy and growth and development over time (McDoweliet et al, 2008). Although several researchers have studied the anthropometry of children, they have most related their studies to nutritional, health and growth aspects (Khor et al, 2009). There are a few studies on the importance of child anthropometry in the design of various child products, specifically toys. Anthropometric measurements are necessary to form the data base which is required for the proper sizing of educational toys. Although the idea of considering child anthropometry in the design for child products is not new, the scarcity of avail-

able sources on anthropometric data among early school aged children calls for more anthropometric research so as to customize the children toys.

With respect to higher education needs, STEM education is more demanding in terms of well equipped laboratories, prototyping needs, as well as building experimental conditions that match the practical world. The pass rate at NUST has been low due to inadequate facilities for STEM enrolled students. 3D printing helps students to bridge the gap between the practical STEM world and the lecture room. Ease of recycling prototypes is also very important to keep the STEM training costs low. 3D printing, coupled with modular design concepts, was proved to be the best choice in cost effectiveness.

LITERATURE REVIEW

This section covers recent, historical and empirical reviews laying the foundation for the present study. Information that is relevant for the anthropometric research for the design of educational toys is presented. The section gives an insight into anthropometry, educational toys and 3D Printing which are the main subjects used to meet the objectives of the chapter.

Anthropometry

Anthropometry is the science that measures the range of body sizes in a population (Pheasant & Haslegrave, 2005). In product design, anthropometrics is the use of body measurements to determine the optimum size for products for comfortable and efficient use. Designers integrate the use of anthropometric data in their design process to optimize the usability and functioning of a product while improving comfort and safety. Advances in 3D imaging technologies have facilitated the collection of these measurements and shapes among the elderly or children (Goto, et al 2015). There are two primary types of anthropometric measurements; structural (static) and functional

(dynamic) measurement. Structural measurements are taken while the body is in a static position. These include skeletal dimensions (joint to joint measurement) and soft tissue measures in contour dimensions.

Dynamic measurements are taken while the body is engaged in some kind of activity like driving a car or reaching for objects. Engineering anthropometry is concerned with the application of both types of data to the design of the products people use.

Child Development Stages

Child development is the change or growth that occurs in children and the gaining of skills in all aspects of the child's life (Frost et al, 2008). It is often divided into three main areas; physical, cognitive, and social-emotional development.

Physical development fall into two main categories:

1. **Gross-Motor Development:** Involves improvement of skills using the large muscles in the legs and arms, such activities include running and bike riding.
2. **Fine-Motor Development:** The coordination of small muscles, in movements, usually involving the synchronization of hands and fingers with the eyes. Cutting, grasping, molding and writing are some of the activities that require fine-motor development.

Cognitive development is about how children learn, think and develop ideas. This is one of the areas of development that is strongly influenced by the experiences a child has. For example learning the names of animals is only possible if a child has been told them.

Social-emotional development is a child's ability to understand the feelings of others, control their own feelings and behaviours and get along with peers (Hoffman, 2013). Social and emotional development involves the acquisition of a set of skills. These include the ability to:

1. Identify and understand their own feelings
2. Accurately read and comprehend emotional states in others
3. Regulate their own behaviour
4. Develop empathy for others
5. Establish and sustain relationships

Educational Toys

The early childhood years are generally regarded as the foundation upon which the rest of an individual's life is built (Rutter, 2002). Educational toys are essential for the proper early development of growing children as they facilitate the mental and physical growth of children. Whenever a child plays with toys, they are practicing life skills. Educational toys enhance intellectual, social, emotional, and/or physical development.

Toys can be divided into several groups, depending on the part of the child they help to develop. Kudrowitz (2010) presented a universal classification system to communicate and ideate new toy concepts to toy designers and students. The system consists of two graphical tools that help designers to classify and manipulate toy product concepts.

Good educational construction toys promote convergent thinking while simultaneously setting the stage for creative, divergent play for children. While they follow the instructions to build the model, children gain skill with the construction pieces. Completing the instructions (convergent thinking) gives them a sense of achievement and reinforces confidence.

Interlocking manipulative toys like puzzles challenge the child to improve hand-eye coordination, patience, and an understanding of spatial relationships. Modern day children are growing up in the greatest era of technological advancements, hence there is need for them to stay in touch with technology. An example of these toys is a remote controlled toy car. Children can be inspired by educational toys which touch on everything from basic STEM to the real physical world. Table 1 outlines the educational toys for the different child development stages.

Table 1. Child development educational toys

Child Development	Type of Educational Toy
Physical or Muscle Development	• Magnetic blocks • Writing tools and scissors • Puzzles • Playground equipment
Intellectual Development	• Card games • Sorting games • Listening games • Books
Creative Development	• Clay • Crayons • Paints • Paper
Sensory Development	• Sand and water toys • Musical instruments • Bubbles
Make-Believe and Social Development	• Dolls • Puppets • Cars and trucks

3D Printing

3D printing is a manufacturing method based on advanced technology that builds up parts, additively, in layers (Ventola, 2014). The 3D printing process starts with a 3D digital model, created using 3D software such as 3D CAD. Table 2 shows different types of 3D printing technologies.

Current and Future Applications of 3D Printing

3D Printing technology is used in the children toy industry (pre-school and primary education), secondary and higher education.

Children Toy Industry

The toy industry is among the biggest beneficiaries of the technology since toys tend to be small and made out of plastic, making it easy to 3D print them. Children can customize their own unique toys by deciding on the features of the toys before they are 3D printed for them. Besides promoting creativity, 3D printing also speeds up and simplifies the making of toys, which in turn lowers the cost.

Table 2. The seven 3D printing/ AM process categories (ASTM, 2014)

Process Type	Brief Description	Related Technologies	Materials
Powder Bed Fusion	Thermal energy selectively fuses regions of a powder bed	Electron beam melting (EBM), selective laser heat sintering (SLS), selective heat sintering (SHS), and direct metal laser sintering (DMLS)	Metals, polymers
Directed Energy Deposition	Focused thermal energy is used to fuse materials by melting as the material is being deposited	Laser metal deposition (LMD)	Metals
Material Extrusion	Material is selectively dispensed through a nozzle or orifice	Fused deposition modeling (FDM)	Polymers
Vat Photopolymerization	Liquid photopolymer in a vat is selectively cured by light-activated polymerization	Stereolithography (SLA), digital light processing (DLP)	Photopolymers
Binder Jetting	A liquid bonding agent is selectively deposited to join powder materials	Powder bed and inkjet head (PBIH), plaster-based 3D printing (PP)	Polymers, Foundry Sand, Metals
Material Jetting	Droplets of build material are selectively deposited	Multi-jet modeling (MJM)	Polymers, Waxes
Sheet Lamination	Sheets of material are bonded to form an object	Laminated object manufacturing (LOM), ultrasonic consolidation (UC)	Paper, Metals

Education Sector Applications

The use of 3D printing in education was investigated by Slavkovsky (2012). Since physical models are important for hands-on active learning, 3D printing technology in education has been used since a while and considered for sustainable development, for secondary education in STEM projects and elementary mathematics education (Pearce et al, 2010; Berry et al, 2010; Lipson, 2007; Lacey, 2010). The best way for students to learn and retain information taught is by applying it to real-life situations. 3D Printing technology is being used in the classroom to offer a highly engaging, hands-on way to teach STEM subjects as well as to expose students to technologies of the future from an early age.

Knill and Slavkovsky (2013) illustrate how 3D printing can help to visualize concepts and mathematical proofs. The new 3D printing technologies make the realization of mathematical models more accessible than ever. Visualization has always been an important ingredient for communicating mathematics (Pedersen, 2005).

Many higher education institutions have re-worked all their lab activities so that they are based on a 3D printing platform. FDM 3D printers are used for most lab workbenches and are customized by installing automation hardware with display interfaces and input/output electronics. These upgrades give students valuable experience using real-world automation equipment.

Schelly et al (2015) investigated the potential of open-source (OS) technologies in an educational setting, given the combination of economic constraints affecting most educational environments. The OS aspect proves to be particularly relevant in the educational setting, as it decreases cost of access and encourages active participation, innovation and improvement through real experience with design and fabrication.

SOLUTIONS AND RECOMMENDATIONS

The section outlines the application of anthropometrics for early school aged children in the design of educational toys. It also covers case

Figure 1. Graph showing the frequency of each skill

study applications of 3D printing in engineering undergraduate studies. Research on existing educational toys and different child development stages was carried out. Concepts were generated from the collected data and the best concepts selected through ranking methods.

Pre- and Primary School Toy Concepts

Relevant data for the design of educational toys was gathered through the use of questionnaires, consultation and ergonomic study. The sample population used included individuals who usually spend reasonable time with children, especially mothers who have information concerning the toys that children play with. The following are some of the questions that were presented in the research instruments and their responses.

1. What are the key skills/educational values that children should acquire from playing with toys?

The majority of the respondents selected literacy and language, maths, science and technology, problem solving and motor skills as one of their choice. Figure 1 summarizes the responses.

Toy property rating for a number of toy properties that are relevant in the design of a toy were outlined in the questionnaire and the respondents had to rate the relevance of each property. Figure 2 summarizes the responses. Some of the responses augment the “Let’s Play!” projects at the University of Buffalo which formulated a number of universal design guidelines for toys (Hinske et al, 2008; Hengeveld et al, 2007).

1. Figure 3 shows a pie chart deduced from the toy attribute survey data. This helps in comparing the value of importance and prioritizing the technical attributes.
2. Based on the various research methods outlined previously, Table 3 summaries the educational requirements of early school aged children and examples of ideal toys to meet those educational requirements.
3. An anthropometric research was carried out in order to come up with children body dimensions that are essential in the design of educational toys.

Table 4 summarizes the mean and standard deviation for the various anthropometry dimensions in a typical source population composed of early school aged children between the age of 6 and 7

Figure 2. Graphical representation of the responses

Figure 3. Pie Chart for toy attributes

Table 3. Educational toy requirements

Research Methods	Educational Values/Requirements	Educational Toy Types
Questionnaire	- Scientific Concepts - Maths and Problem solving - Literacy and language	- Electronic Toys - Puzzles - Computer Toys - Dolls - Drawing Sets
Consultation	- Read and write - Informal/ Formal Communication - Mathematical calculation	- Building Toys - Mechanical Toys - Make-believe Toys - Art and craft Toys - Word Construction Toys - Phonic Toys
School Syllabus/ Primary school Curriculum	- Spoken English/ Communication/ Identifying - Addition and subtraction of number up to 20 - Division and multiplication - Counting - Cognitive and physical development - Tell clock times - Art and craft/Drawing	- Clock toys - Reading Cards - Abacus - Art Material - Story Books
Literature Review	- Cognitive - Social - Physical development	- Construction Toys - Puzzles - Musical Instruments - Pattern Making Toys - Transportation Toys - Jumping Ropes

Table 4. Anthropometry dimensions

years. Children in this age group will be attending primary school, either in grade 1 or grade 2.

Developed Toy Concepts

Toy concepts for three educational values were proposed. The three educational values deduced from Table 3 are:

- Scientific Concepts
- Mathematics and Problem Solving
- Literacy and Language Skills.

The dimensions of the final toy models for 3D printing were based on the anthropometric data presented in Table 4.

Concept for Scientific Toy

The Balloon Boat in Figure 4 was designed to move on water by the deflation of a balloon. The child blows up the balloon, closes the balloon opening by fingers then places the boat on top of water,

Anthropometry Dimension	Mean, μ (cm)	Standard Deviation, SD
Standing Height	109,6	2,5
Sitting Height	78,2	1,8
Standing Shoulder Height	81,6	1,3
Sitting Shoulder Height	55,2	1,5
Standing Eye Height	98,9	2,2
Sitting Eye Height	72,1	1,3
Sitting Elbow Height	40,5	1,6
Chest Breadth	19,3	0,8
Shoulder Breadth	29,8	1,0
Elbow-Hand Length	31,3	1,5
Shoulder-Elbow Length	24,7	1,9
Palm Length	13,4	0,3
Palm Width	6,2	0,1
Thumb Width	1,5	0,1
Thumb Thickness	0,9	0,1
Minimum Holding Distance Between Thumb and Index finger	2,1	0,2
Holding Distance Between Thumb and Middle Finger	5,4	0,3
Forward Reach	47,3	1,3

Figure 4. Scientific toy

remove their finger and observe what happens. A rubber band is added on top to secure the balloon.

- **Advantages:**
 - Incorporates fun scientific concept
 - Offer opportunity to learn something new
 - Active participation of child during use
- **Disadvantages:**
 - Use of very light material for the boat
 - Require a wide container of water
 - Frequent balloon replacement

Concept for Literacy and Language Toy

Reading cards and construction toys are used to acquire reading and spelling skills that will

Figure 5. Literacy and language toy

obviously lead to better communication skills. The word construction tool and reading card are combined to come up with toy shown in Figure 5.

E

- **Advantages:**
 - Word construction skills
 - Spelling skills and reading skills
 - Overall improvement of language skills
- **Disadvantages:**
 - Does incorporate writing skills

Mathematics and Problem Solving Concept

The concept shown in Figure 6 combines the counting frame and the mathematics calculator to come up with the mathematics and problem solving toy.

Engineering Design Course Instruction

3D printing can serve as the best platform to deliver lectures and typical design assignments to undergraduate students in engineering. Two

Figure 6. Mathematics and problem solving toy

Figure 7. System architecture

projects are illustrated: online 3D printing mass customization platform and ready-to-use 3d printed gardening implements.

3D Printing Mass-Customization Design Project

3D printing offers opportunities for mass customization. An online system which can be used in customizing 3D printed products is under development at NUST. The system automatically generates the product as specified by the customer. Students and course instructors use the system to promote innovation and design thinking.

System actors for the Mass Customization include the administrator, and users. The administrator administers the system, adds, modifies and deletes product design templates. Users can modify and customise product templates. The system architecture and home page are shown in Figure 7 and 8 respectively. A similar application was conducted at Griffith University (Loy, 2014). The research considered the potential of 3D printing as an eLearning tool for design education and the role of eMaking in bringing together the virtual and the physical in the design studio.

Table 5 shows the product template, a cubic penholder that the customer uses to personalise the diameter and colour of the pen. It can be used for crayons, pencils and markers.

3D Printed Gardening Implements Design Project

Research on possible gardening implements design was carried out as part of an undergraduate engineering design course. Having explored a variety of possible designs, the best design of the gardening implements was chosen and optimized for 3D printing. The printed models can be further subjected to the testing phase to see if they meet the design requirements and to determine their efficiency. After satisfactory performance, the digital models of the designed gardening implements were uploaded on a website. The website consists of ready to print 3D gardening implements and farmers from all over the world can access them hence eliminating the need for farmers to be experts in CAD software for designing their own implements.

Three leading factors to consider during the design of 3D printed gardening implements were

Figure 8. The home page

Table 5. Output system for penholder template

Parameter Input	System Output
Customise Colour: Blue Pen Radius 0.5 Update ☐ Instant Update Submit	
Customise Colour: Yellow Pen Radius 1 Update ☒ Instant Update Submit	

found to be simplicity, portability and durability. These weights are shown in Figure 9.

One chosen concept based on design attributes is illustrated in Figure 10. The design has a spinner for the sprinkler to be mounted on top of the sprinkler and will be rotating under the water

pressure distributing water evenly throughout a 360° angle. Due to the pressure of the water there is need for a mechanism to firmly hold the two together while leaving room for free rotation of the spinner.

Figure 9. Design attributes for gardening implements

Website for Gardening Implements Ready for 3D Printing

A website which anyone could access from anywhere to upload and/or download STL CAD files ready for printing was designed as part of the engineering design course. The domain name for the website is <http://anenyasha3dprints.com/>. The website is shown in Figure 11.

FUTURE RESEARCH DIRECTIONS

3D printing has three major weaknesses which are time consuming, mechanically weak printed models, and limited material selection.

Future research should concentrate on making the process faster as well as multi- material and colour printing. This would reduce the inventory

of 3D printers in laboratories whilst enabling students to build as many models within short time frames. Product specific research will boost the database of design for manufacture and assembly (DFMA) rules for 3D printing as well as designing ready for use 3D printed products.

The wide use of smart phones and data connectivity has caused a lot of boom in the design of mobile applications (Apps) for software products that traditionally demanded more resources from desktop computers. More mobile Apps can be designed in future that focus on 3D printing. There are quite a number of softwares that can be used for non-designers to customise their products. They are both online and offline. Programmers can make use of the free libraries offered by OpenJscad, OpenCascade, PythonOCC and many others to design products that are customisable.

Figure 10. Sprinkler design for 3D printing

Figure 11. Website for gardening implements ready for 3D printing

Nowadays, e-Learning systems are on the increase and more focus is being directed towards mobile platforms. Since 3D printing is highly promising in the education sector, future research should focus on integrating 3D printing Apps to e-Learning systems. A number of CAD vendors are now offering cloud based solutions to their industrial and educational software solutions. Major examples are AutoDesk and Solid Works. This helps in democratising design and CAD modelling since the approach eliminates the need for high speedy computers. Therefore, picking up lessons from the trend to design 3D printing Apps

that can design digital models as well as actually command 3D printers from the students' remote comfort will be a perfect integration to the boom of e-Learning systems.

There is also a limited range of educational toys custom designed for children with disabilities. These children play with toys that do not suit their conditions in term of educational value, anthropometric dimensions, social and mental development. Therefore the design and customisation of educational toys for these children is a very important consideration for further work.

CONCLUSION

The chapter outlined anthropometric research for the design of educational toys which can be 3D printed for ready use. It has also shown how the technology can be used to cost-effectively allow institutions to offer their students state-of-the-art laboratory platforms, which match industry practice. 3D printing is proving to be the best platform for in-class instruction as well as for carrying out practical world design assignments. This was illustrated through two design projects carried out by engineering students in a design course; 3D printing mass-customisation for mini-office products and design of 3D printed ready to use gardening implements. Future research prospects have been highlighted, which include integration of 3D printing into the emerging mobile e-Learning platforms, as well as taking advantage of the cloud platform to offer Apps that allow digital object modeling for 3D printing.

KEY TERMS AND DEFINITIONS

3D Printing: A radically different manufacturing method based on advanced technology that builds up parts, additively, in layers at the

sub millimeter scale. Also known as Additive Manufacturing.

Anthropometry: The science that measures the range of body sizes in a population.

CAD: A software for 2D and 3D digital modelling of objects.

Educational Toy: A toy that helps a child learn something good, something that will help in the future.

e-Learning: Learning conducted via electronic media, typically on the Internet.

Ergonomic Design: A safe and comfortable design or product achieved through the use of anthropometric data to optimize the usability and functionality.

Mass Customization (MC): A business strategy that aims to provide customers with individualized products at near mass production efficiency.

STEM: A curriculum based on the idea of educating students in four specific disciplines — science, technology, engineering and mathematics — in an interdisciplinary and applied approach.

STL (STereoLithography): A standard file type (triangulated representation of a 3D CAD model) used by most additive manufacturing systems.

Tools, Pedagogical Models, and Best Practices for Digital Storytelling

Jari Multisilta

Tampere University of Technology, Finland

Hannele Niemi

University of Helsinki, Finland

INTRODUCTION

Sharing photos and short videos with others has become increasingly popular among youth. Using social media services, users share events and moments from their daily lives. Östman (2015) defined this phenomenon as *life-publishing*. Examples of life-publishing include the growing use of Snapchat and Periscope social media services among youth. According to Piwek and Joinson (2016), Snapchat users mainly share “selfies,” and they mostly use the service at home. Although sharing videos is a common activity among youth, schools are not using digital videos for learning. There is a need to study the pedagogical models that could be used in designing classroom activities involving the use of digital videos.

In this chapter, digital video storytelling refers to learning activities that involve the creation and use of digital video. According to Ladeira, Marsden, and Green (2011, p. 431), “digital storytelling typically seeks to preserve and disseminate real-life, non-fiction stories.” In a learning context, digital storytelling involves the creation and distribution of content that is used in the learning process as well as the interaction between the users of the content. Digital storytelling that includes user-generated content has been used in preserving personal experiences (Ladeira, Marsden & Green, 2011), mobile collaborative live video production, such as in an event in which a Video Jockey (VJ) mixes the video feed using

the audience (Engström, Esbjörnsson & Juhlin, 2008), and in collaborative learning (Niemi, Harju, Vivitsou, Viitanen, Multisilta & Kuokkanen, 2014; Niemi & Multisilta, 2015; Tuomi & Multisilta, 2010; Wolf & Rummmler, 2011). In this chapter, digital video storytelling will be discussed in the context of learning.

Digital video storytelling can be seen as an approach to learning twenty-first century skills. Taking advantage of the creative potential of modern communication technologies, students can work together, explore their ideas, and become creators, producers, and active learning participants. Twenty-first century skills have become a key topic on the agendas of education systems worldwide. Educators are required to seek new forms of teaching and learning for the future. The challenge is determining how to motivate students to learn and become engaged in learning. Digital video storytelling can assist in motivating students by bringing technologies they use in their free time into the school environment.

In this chapter, pedagogical models, examples, best practices, and outcomes that illustrate how students become engaged and motivated when using digital storytelling in knowledge creation in cross-cultural settings will be presented. The results are based on the empirical data and findings from several international pilots.

A review of existing tools and practices for digital video storytelling will be presented. The results show that students can become highly

engaged in learning through digital storytelling. The research data indicate that engagement in digital video storytelling is a combination of a joy of learning (fun) and a commitment to hard work.

BACKGROUND

The use of videos on the Internet has been expanding rapidly in the last few years. Although the most popular web video content is related to music videos and entertainment, web videos can have several educational uses. Khan Academy (www.khanacademy.com) is an example of a web video service that has a large collection of educational videos. According to Talbert (2012, para. 7), “Khan Academy is a collection of video lectures that give demonstrations of mechanical processes.” Considerable debate has taken place regarding the pedagogical model used at Khan Academy (Prensky, 2011; Talbert, 2012; Thompson, 2011). The main criticism is that Khan Academy is not supporting a constructivist learning model in which learners actively create knowledge using activities that support knowledge construction.

The creation of video stories by the learners themselves is considered a more effective way of using video in learning. According to Correia et al. (2005, p. 1), “the ability to have constant access through mobile devices allows a new way of doing cinematographic narratives that can enhance the participants’ experience in a significant way.”

Video stories can be interactive (Ladeira, Marsden and Green, 2011) or generated in real time with scripting (Vaucelle & Davenport, 2004). Storytelling platforms can also support automatic story creation (Multisilta & Mäenpää, 2008; Zsombori, et al., 2011). Multisilta et al. created a mobile social media service for community created videos (Multisilta & Mäenpää, 2008). MoViE, the *Mobile Video Experience Platform*, is a research platform for studying how people create video stories and how they share and learn with mobile social media. MoViE has been used both in primary and secondary schools (Tuomi &

Multisilta, 2010) as well as in higher education (Kiili, Multisilta, Suominen & Ketamo, 2010).

Digital stories have also been used to preserve, reflect on, and share the life experiences of people who do not have access to personal computers and who are living in rural areas in South Africa (Bidwell, Reitmaier, Marsden & Hansen, 2011). Digital story creation may also be able to provide a means of exploring self-identity through the sharing and group construction of digital video stories (Vaucelle & Davenport, 2004).

LEARNING USING DIGITAL VIDEO STORYTELLING

Pedagogical Models

In this subchapter, two pedagogical models for using digital videos and storytelling will be presented. The aim of the pedagogical models is to provide teachers with a sound basis for applying digital video storytelling tools in their own classrooms. The global sharing pedagogy and video inquiry learning models are both based on theoretical work that has been evaluated in empirical research projects.

As a pedagogical method, digital storytelling builds on learner-centered approaches that can improve students’ learning in several ways (Kearney, 2009; Yang, 2012). According to Niemi et al. (2014), learning with digital storytelling is seen as a socially and culturally related process that takes place in the interaction between a learner and material tools, psychological tools, or other human beings (Vygotsky, 1978). In this sense, it builds on the constructivist learning model. Learners play a central role in exploring and building knowledge by using tools available in the digital learning environment. Students also interact with psychological tools when using language, brainstorming, or creating stories. Learning with others can take place when creating video stories with peers and watching stories that other students have made. When planning and making

digital stories collaboratively, students can become aware of their own knowledge and experiences and reflect on and share these experiences with others. Watching other students' stories can also create new perspectives on topics and promote the understanding of a certain phenomenon (Niemi et al., 2014).

Global sharing pedagogy supports Vygotsky's ideas of learning (Vygotsky, 1978). According to Vygotsky, learning happens in social activity and higher mental functions are mediated by tools and signs. In addition, learning happens in the zone of proximal development, that is the difference between what a learner can do without help and what he or she can do with help. The help can be provided by the teacher or by the peer learners. In addition, Vygotsky pointed out that there is a close connection between learning, thinking, and the language. The language can be seen as a tool for both social activity and thinking.

In global sharing pedagogy, learning is a mediated activity with tools, signs, and social interaction. According to Niemi et al. (2014), there are four mediators of learning in the global sharing pedagogy: 1) *learner-driven knowledge and skills creation*, 2) *collaboration*, 3) *networking*, and 4) *digital media competencies and literacies*. The mediators contribute to the learners' engagement in the learning activity. Niemi et al. (2014) illustrated that engagement in the digital video storytelling activity could be divided into two components: joy of learning and hard work. With the use of digital tools, learning can happen both in social context and through individual learning.

Inquiry learning is defined as "an approach to learning that involves a process of exploring the natural or material world and that leads to asking questions, making discoveries, and rigorously testing those discoveries in the search for new understanding" (de Jong & van Joolingen, 2008, p. 458). In an earlier study, the researchers found that students find it difficult to argue and reflect on what they see in the video clips and video stories they and their peers have produced; however, argumentation, reflection, and commenting are important 21st century skills (Niemi et al., 2014).

In video inquiry learning, the learners and teachers capture mobile video recordings of events and phenomena that prompt questions from students and that serve as a basis for inquiries and collaborative learning in the Science, Technology, Engineering, and Mathematics (STEM) disciplines. Video inquiry learning is closely related to higher order thinking skills. According to Lewis and Smith (1993), higher order thinking consists of problem solving, critical thinking, creative thinking, and decision making. They explained that "higher order thinking occurs when a person takes new information and information stored in memory and interrelates and/or rearranges and extends this information to achieve a purpose or find possible answers in perplexing situations" (Lewis & Smith, 1993, p. 136). The definition clearly describes the process of inquiry video learning in which learners create video clips or video stories and argue, reflect, and comment on the content of the videos they and their peers have recorded and shared through social media.

Tools

There are different types of learning tools that can be used in digital video storytelling: 1) Learning Management Systems (LMS), 2) stand-alone video editors, and 3) video sharing sites. Several learning environments and LMS include an option to upload video files and share files with other users; however, such systems are not designed for digital video storytelling because they do not have editing or remixing features and their collaboration features are limited. Instead, their purpose is to manage class activities, deliver content, provide a platform for submitting exercises, and assess student activities. The stand-alone video editor software do not support sharing and collaboration. They provide a wide range of effects and tools for adding music, titles, and subtitles to video.

In this subchapter, five video sharing sites are compared based on a set of requirements that are typical for classroom use. The video sharing sites were selected based on the discussions with teachers. YouTube (www.youtube.com), Vimeo (www.vimeo.com),

vimeo.com), and WeVideo (www.wevideo.com) are popular video sharing services; TeacherTube (www.teachertube.com) is one of the oldest video sharing sites for teachers and MoViE (cicero-movie.edu.helsinki.fi) is one of the more recent video sharing sites targeted for learning.

The following features were reviewed:

- Access (how to sign on to the service).
- Content moderation.
- Editing capabilities.
- Possibility to do annotations to the content.
- Possibility to use analytical data from the user activities.
- Privacy settings.
- Existence of content grouping and channels.
- Limitation of what kind of content that can be uploaded to the site.
- Pricing model.
- Pedagogical support.

It is important to have an authentication system, but there are different regulations in different countries, such as how old children should be to have an Internet identity. For classroom use, it is important that the teacher is able to moderate the content to prevent the use of inappropriate content. Digital video storytelling often requires the remixing and editing of videos. In many cases, the learners create their stories by recording several short video clips that they edit and remix later. This can be done using a stand-alone video editor or video editing features provided by the video sharing service. Annotations allow for adding small comments over the video. These comments could be used as questions, or they could include important information related to the learning content. For example, a teacher could add an annotation to the video to remind students to pay attention to a specific event in the video. Statistical data provide information to the users regarding the use of the content and could potentially be very useful for teachers, but, so far, the video sharing sites do not have effective learning analytics tools.

Privacy, content, and cost are also important features for video sharing sites that are used in schools. All the reviewed systems have privacy settings for individual videos and groups. It is important to be able to create working areas for a class or a group of students, so that they have their own space where they can collaborate and share the videos. When schools and teachers are considering which video sharing site to use, it may be important to investigate what type of content is used in the service. Although a closed working area would be created on the site for students, the existence of entertainment content in the same system decreases the credibility of the system. Many systems are free or have a free trial option; however, the free access may include.

Most video sharing sites allow registered users to upload videos to the service and to set privacy limitations for the videos they have uploaded. Moreover, most video sharing sites are not designed for learning. Many video sharing sites allow users to watch videos, but uploading your own content requires registration either with the service or using a Facebook or Google identity. For schools, this may be a problem because in many countries 13 years is the minimum age that is required to sign up for Facebook or Google (Table 1).

YouTube, WeVideo, and MoViE have a video editor that can be used to do simple trims (YouTube), remixing (MoViE), or full video edits with sound and effects. YouTube and MoViE have a useful feature for annotating the videos. By using annotations, students can add subtitles that appear and disappear at certain times over the video. By using annotations, students could ask questions and make comments on the video. Some video sharing sites provide analytics tools for the owner of the video clip. Typically, the owner can see how many times the video has been watched and, in some cases, from where the watchers are geographically. Tools that could provide learning analytics to teachers would be very useful, but the systems do not have this feature yet. Moderation is also an important characteristic for teachers,

Table 1. Access and moderation of the content

	Access	Moderation
YouTube	Google UID	No
Vimeo	Vimeo UID, Facebook UID	Channels can have moderators.
WeVideo	Facebook UID	No
MoViE	MoViE UID	Yes
TeacherTube	TeacherTube UID	Content moderated by the service staff; content flags.

since it helps in preventing inappropriate content from being shared on the site. For TeacherTube, the service providers moderate the content. In MoViE and Vimeo, the teacher or channel owner can moderate the content. TeacherTube also has a red flag system in which users can flag inappropriate content for review by the service providers (Table 2).

All the reviewed video sharing sites have a method to create a specific working area, which is called a channel, album, project, group, or collection, depending on the system. The basic idea of the working area is to separate access for a certain group of people, who can share and access materials within. Only MoViE and TeacherTube have pedagogical concepts included in the service. TeacherTube includes features from LMS (such as a class management), but it is effective in utilizing the creation and delivery of video content (Table 3).

Best Practices

A digital video story can be created on almost any topic using several different methods. Table 4

shows examples of the video storytelling projects that the researchers have been implementing. In total, over 2000 video clips were created during the interventions. Some of the topics were performed similarly to a drama, that was scripted with roles and actors selected and camera angles planned well ahead. Other topics mimicked documentaries and included interviews of the subjects. In some classes, it was not possible for the students to appear in the video clips. In these cases, students created animations using self-drawn paper dolls, or they created and presented a series of slides with narration. As a result, in all of the videos the students' voice was strong. The teachers and the researchers helped the students complete the manuscript (Penttilä, Kallunki, Niemi & Multisilta, 2016). In addition, the students needed help in selecting the shooting locations so that the sounds from the surrounding environment did not significantly affect the final outcome. Many videos were shaky because they were recorded using a mobile device that was not attached to a tripod. The students showed creativity, such as in adding a background soundtrack from a music player to the video clips while recording.

Table 2. Edit, annotations, analytics, and privacy

	Edit/Remix	Annotations	Analytics	Privacy
YouTube	YouTube editor	Yes	Google analytics	Videos and channels can be private.
Vimeo	No	No	Simple statistics	Videos can be private.
WeVideo	Editor	No	No	Yes
MoViE	Limited editing	Yes	Google analytics available for research purposes.	Yes
TeacherTube	No	No	No	Videos can be private.

Table 3. Grouping, content, price, and pedagogical concepts

	Groups	Content	Price	Pedagogical Concepts
YouTube	Channels	Everything/not school content only.	Free	No
Vimeo	Channels, albums	Everything/not school content only; channel owner can set the content for all or mature audiences.	Basic is free.	No
WeVideo	Projects	Everything/not school content only.	Basic is free.	No
MoViE	Groups	School-related content.	Free	GSP, VIL, questionnaires.
TeacheTube	Groups, channels, collections.	School-related content.	Free, advertisements	Lessons, questionnaires, classroom management, badges.

Table 4. Examples of digital video stories

Topic	Exercise	Example
Local history	Create a video story of a historical event in your own school, neighborhood, or city.	• A drama of Greek mythology. • An interview of a local Nobel prize winner. • A paper doll animation of the immigration of Europeans to the USA in 1820-1930
Influencing opinion	Create a video story of an issue or cause for which you would like to raise awareness.	• A drama of homelessness. • The use of animals in testing cosmetics.
Chemistry lab	Document the chemical experiment you are doing.	Close-up video clips of a chemical process (for example, how to create a superball using polymerization).
Physics	Create video clips of a physical phenomena.	Video clips of circular motion (the clips can be recorded outside the classroom).
Mathematics	Do your own Khan Academy video.	Create a video of a solution of a mathematical exercise using a pen and paper.
Biology	Study the circulation of water.	A narrated PowerPoint presentation with video clips recorded at the local lake or river.

SOLUTIONS AND RECOMMENDATIONS

Niemi and Multisilta (2015) studied the methods of engagement in collaborative video work for learning. Based on these authors' findings, students can become highly engaged in a learning activity through digital storytelling. In addition, engagement can be defined by two components: an emotional aspect (joy of learning or fun) and a commitment to hard work. Using digital video storytelling, students learn several 21st century skills when producing learner-driven content. In addition, working in groups is important for student motivation and enthusiasm. The digital environment was shown to be the best predictor of

both engagement and learning outcomes (Niemi & Multisilta, 2015).

The findings provide evidence that students enjoy creating digital videos. They work actively, seeking new knowledge and constructing their videos using different information sources. A general observation is that they also self-evaluate their work. It was observed that commenting on others' work was difficult for students. Giving and receiving feedback is not self-evident. Although students find it interesting to watch others' videos, making active comments is still fairly uncommon.

For the Video Inquiry Project (VIP), design-based research and development was conducted to establish a broadly scalable approach for K-12 learners and teachers to capture mobile video

recordings of events and phenomena that prompt questions that can serve as a basis for inquiries and collaborative learning in the STEM disciplines (Multisilta et al., 2014). During the VIP project, it was found that digital media, including video, can provide an important nexus attracting joint attention of peer learners or learners-and-a-teacher, catalyzing learning conversations in-the-moment. Video can also play an important bridging function, connecting and spawning learning events across settings (including school and home) and generating discussions about math, science, and engineering. These conversations provide opportunities to ask questions, express confusion, share perspectives, and provide explanations. Learner-generated videos also provide a sense of agency and ownership that is engaging.

There are several kinds of tools that can be used for digital video storytelling. Some tools can be used only for editing the video content while others have capabilities to share the video to others and collaborate with other learners. Most of the tools are available on the web, but have not been designed to be used for learning. In addition, there has been a wide discussion on if schools should block the access to YouTube and similar sites (Storm, 2012) because of the availability of distracting content. It should be on the teacher's responsibility and right to select a pedagogical model and tools and apply them in the classroom in a meaningful way. So far, global sharing pedagogy and video inquiry learning models have been illustrated to provide engagement for STEM learning.

FUTURE RESEARCH DIRECTIONS

There is a growing need to seek new methods to understand the learning process in digital learning environments. Digital learning environments can be designed so that they collect various data from users while they use the environment and interact with other learners; however, these data are often either not available or not very useful for teach-

ers. Learning-related user data could be utilized so that they provide support in understanding the learning process in a much deeper way. In order to do so, learning data should be collected and analyzed in relation to the content. The data should be visualized so that teachers could immediately understand their meaning in relation to the class and the lesson. New methods and tools for collecting, analyzing, and visualizing learning analytics data in inquiry-video-based learning are needed.

General analytics tools, such as Google Analytics, can be used to evaluate the use of a digital video storytelling service, but it only provides largely superficial information regarding the learning process. Generic data collected by the existing analytics systems include web navigation data, such as page hits, the number of visitors to a page, and the time spent on the page. By utilizing data from the content and from the learning activities, teachers could understand the learning process in a more meaningful way.

CONCLUSION

By using digital video storytelling, students can engage in a variety of learning activities that could also be done outside the classroom, at home, at a sports field, or at a museum. Students already use videos often in their free time, but schools are not utilizing the expertise students have in publishing their lives in a digital space. By utilizing digital video storytelling as a tool in a classroom, students learn twenty-first century skills, such as creativity, problem solving, and collaboration.

Students need teachers' guidance in creating the manuscript and planning the video shooting locations. The stories can be dramas, plays, animations, narrated presentations, documentaries, and interviews. In the stories, the student's own voice is strong.

In the chapter, five video sharing sites were compared based on a set of requirements that are typical for classroom use. All the tools were available on the Internet. None of the tools reviewed

will support all classroom requirements. In the end, it is up to the teacher to decide the best tool for the particular case in the classroom.

KEY TERMS AND DEFINITIONS

Constructivist Learning Model: Learners actively create knowledge using activities that support knowledge construction.

Digital Video Storytelling: Learning activities that involve the creation and the use of digital video.

Global Sharing Pedagogy: Learning is seen as a mediated activity with tools, signs, and social interaction. Global sharing pedagogy has four mediators of learning: 1) learner-driven knowledge and skills creation, 2) collaboration, 3) networking, and 4) digital media competencies and literacies. The mediators contribute to the learners' engagement in a learning activity.

Inquiry Learning: Learning activities where learners search and construct new knowledge by exploring the world or the phenomena, by asking questions, making hypothesis, and testing the hypothesis.

Life Publishing: The use of social media services in which the users are sharing events and moments from their daily lives.

Twenty-First Century Skills: A set of knowledge and skills that are or will be important to succeed in the future world. Examples of twenty-first century skills include creativity, communication, collaboration, digital literacy, and problem-solving skills.

Video Inquiry Learning: Learning is based on the investigation of questions, scenarios, or problems using videos that students create and share using digital video storytelling tools. The videos prompt questions and serve as a basis for inquiries and collaborative learning.

The Use of Podcasting/ Vodcasting in Education

E**Athanasios T. Stavrianos***2nd Technical Vocational School of Xanthi, Greece***Apostolos Syropoulos***Greek Molecular Computing Group, Greece*

INTRODUCTION

The terms podcasting and vroadcasting refer to automatically downloadable audio and video files. Typically a podcast is an MP3 file whereas a vodcast can be any popular compressed video file. In 2004 the term podcasting was first mentioned in an article in the newspaper *The Guardian* (Hammersley, 2004). The term podcasting derives from iPod, the device that was first used to download and play podcasts. The inventors of the technology are Dave Winer and Adam Curry (Brown & Green, 2007). At that time, Winer was a software developer and an RSS evangelist while Curry was an MTV vj. Rich Site Summary, or just RSS, is a format for delivering regularly changing web content. Initially, podcasting was used for personal entertainment or information but soon it became clear that it could be used in education. Since its introduction the technology became very popular and this can be seen by the number of downloads. In April of 2006 ten million podcasts were downloaded while in November of the same year 17 million podcasts were downloaded.

The terms podcasting and vroadcasting (the vod part comes from *Video On Demand*) refer to a process. In particular, when there is an event, one has to capture the song, the interview, etc. The result can be either an audio file or a video file. Today's video capturing devices can produce high definition video that is stored using a compressed codec so there is no need to re-encode the video, something that was quite common in the early

days. Then, one had to post this audio or video file to a web site or a blog and using an RSS (Rich Site Summary) envelope (RSS is a format for delivering regularly changing web content). Obviously, the author had to inform people who might be interested in the new content. This is done automatically if people subscribe to an RSS feed. Nowadays one can use her smartphone to read the RSS feed and then to download the new content.

Today one can use a smartphone to record a video file or an audio file. Also, one can use a digital camera to record a video file. When one prepares a podcast, then it is recommended to use the "Audacity" open source software for audio editing. On the other hand, the open source project "pitivi" can be used to edit video files.

BACKGROUND

Podcasting was primarily used in tertiary education to make lectures available to students in order to clarify difficult parts and emphasize important ones. Later on, podcasts were replaced by vodcasts. Currently, there are four kinds of vodcasts that are used in education: lecture-based, enhanced, supplementary, and worked examples (Kay, 2012). A lecture-based or "substitutional" vodcast is a recording of an entire lecture. Thus students can experience what happened in the lecture hall without actually being physically present. An enhanced vodcast is video footage of a slideshow (e.g., Powerpoint or Beamer presentations) that is

presented with an audio explanation. Supplementary vodcasts are designed to augment the teaching and learning of some courses and may include administrative support, real-world demonstrations, summaries of lectures or textbook chapters, or additional material designed to broaden or deepen student understanding.

There are also other ways to classify vodcasts. For example, depending on whether a vodcast is offered in segments or not, one can talk about segmented vodcasts or non-segmented vodcasts, respectively. In addition, the pedagogical strategy can be used to categorize vodcasts. In particular, there are three different teaching approaches. The first is called receptive viewing and includes vodcasts to be viewed by students in a passive manner (i.e., like watching a movie). There are problem-solving vodcasts that are designed to explain and help students in learning how to solve problems and exercises related to their courses. Naturally, such vodcasts are useful for people who study science, mathematics, or engineering. A third category includes vodcasts that are created by students for students.

Although vodcasts seem to be quite popular today, there are a few questions related to their use in education. The first question is whether students are ready for this technology and the second question is whether this technology is actually useful. The first question has been tackled by (Walls, Kucsera, Walker, Acee, McVaugh, & Robinson, 2010) among others. First we need to note that today most if not all students own laptop or desktop computers and smartphones, which can be used to listen to music, to watch videos, take pictures, shoot videos, and so on. Thus many of the devices of the past (e.g., iPods, mp3 players, pocket digital cameras, and so on) have been replaced by smart-phones. This simply means that all students have the potential to create, download, and watch vodcasts. It has been suggested that vodcasting can improve student learning outcomes. This suggestion is largely based on Mayer's cognitive theory of multimedia learning (Mayer, 2001). According to this theory

“an individual's information processing system includes separate cognitive channels to process visual/pictorial and auditory/verbal stimuli; in this respect, learning is obtained by integrating information between such channels” (Walls, Kucsera, Walker, Acee, McVaugh, & Robinson, 2010). In different words, there is a limit to what a learner can achieve. Thus when a learner is presented with a large amount of pictures, images, talks, sounds, etc., hence she might fail to comprehend most of this information. Not so surprisingly, vodcasts can solve this problem! How? Each student will have the opportunity to watch vodcasts in the comfort of their room or in any other place that may suit a student. More importantly, students can control the speed and pace by which they will watch specific content.

Of course vodcasting is not a panacea and so it has certain limitations. For example, when students are already using a variety of resources in their studies (e.g., text-books, lectures notes, etc.), then adding one more kind or resource may create some sort of cognitive overload. Although students own smart-phones and other related technological “gadgets”, still they use them for entertainment and not for their studies. Therefore, it is not obvious that students would consider using their smartphones in their studies, particularly in institutions that have not used vodcasts in their educational resources. It has also been argued that the use of vodcasting may provide a justification and excuse for students to skip classes. However, some studies have revealed that students do not consider a vodcast as a substitute for attending a lecture. After all, one cannot ask a vodcast questions!

According to findings provided by (Walls, Kucsera, Walker, Acee, McVaugh, & Robinson, 2010) students do not find vodcasts particularly useful in their studies. They think that supplementary vodcasts contribute something in their learning. Also, students utilize vodcasts in rather different ways and in rather different circumstances. According to this study, they might utilize vodcasts during trips, while eating or exercising, and while study-

ing. Based on these findings one could conclude that students are not particularly ready. However, students become ready when they realize that a particular technology can be really beneficial in their studies.

A study that is documented by (Fernandez, Simo, & Sallan, 2009) examined the usefulness of vodcasting (the authors use the term video podcasting which has been substituted by vodcasting). Based on a number of principles of good practices aiming to improve students' learning process in undergraduate studies, the authors examined if these are achieved with the use of vodcasting. Briefly, these principles are:

1. Active learning is more effective than passing learning;
2. Learning demands students to be focused and aware of the importance of what they study;
3. Students learn more effectively when they have reasonable and positive goals that coincide with the goals of the instructor;
4. New knowledge must be connected to previous knowledge;
5. Information must be organized in personally meaningful ways;
6. Students need feedback to check their learning progress;
7. Unlearning what has been learned is more difficult than learning new things;
8. The way students are assessed affects the way they study;
9. Mastering a skill or a body of knowledge takes a lot of time and energy;
10. Learning to apply known ideas to new contexts is quite difficult;
11. High expectations may lead to great achievements;
12. Teachers have to balance levels of intellectual challenge and instructional support;
13. Motivation to learn is never steady; and
14. Teachers and students must always interact.

Students that participated in this study hoped that vodcasts would render attending classes useless. However, this was not the case as vodcasts cannot replace a textbook, which is something these students learned soon after the experiment started. Of course, all students found out that vodcasts can be used in any place and at any time, something that is particularly convenient. Most students used vodcasts in order to get prepared for new lectures. This way they knew the difficult parts of the lecture so they could prepare questions in order to clarify things. In general, this experiment showed that vodcasts are particularly useful.

So far we discussed the use of vodcasts in tertiary education. However, their usefulness in secondary education has also been studied (Coutinho & Rocha, 2010). In this study the authors present the "Geomcasting" project whose goal was the creation of vodcasts and *screencasts* (i.e., video made of screenshots that is accompanied by narration) by students so to help other students to pass the descriptive geometry class. The students involved created content for different parts of the class and the resulting content was uploaded to a blog site for future use. The authors of the study noticed that students were quite happy with their participation in the project and also those that used the content in their own studies found it particularly useful.

THE EZCAST CASE

So far we have given a general presentation of the technology and its use in education. In passing we mentioned how one can create content and make it available but we did not say anything about modern platforms that really facilitate the creation and sharing processes of vodcasts. In October of 2015, the first named author attended a presentation that took place in an auditorium of the Université libre de Bruxelles (ULB).¹ The presentation was about innovative educational technologies that the

teaching staff of the university developed and is actually using. In particular, the attendees were introduced to the *EZcast* (pronounced *Easy Cast*) web application that allows lecturers or teachers to share media contents with an audience. In addition, it was demonstrated how university students are using and interacting with the platform. Also, they had the chance to watch sample videos and learn about the hardware infrastructure used to record, manage, and upload multimedia content. Naturally, the presentation did not give the full details of every aspect of the project, nevertheless, it was enough for most participants to start studying all relevant details of the platform.

The Development Process

EZcast (EZcast wiki, 2014) along with its front-office component EZplayer (Roland, 2013), was officially launched by the Université libre de Bruxelles at the beginning of the academic year 2013-2014 and was made available to all students. The project evolves rapidly and this means that new releases will be available soon.

The implementation principles of the EZcast platform are a mixture of a design-based research approach (Collective, 2003) and a systemic user-centric approach (Roland, 2013). Design-based research aims at improving the educational practices using methods such as iterative cycles of analysis, design, enactment and redesign, constant collaboration between researchers and practitioners (Wang & Hannafin, 2005) leading to the production of a device (in this case the EZcast platform) and at the same time the introduction of new principles and theories. Based on this theoretical framework, ULB conducted a survey for three years collecting quantitative (5399 students answered questionnaires) and qualitative data (52 students were interviewed). The survey measured the way students use a vodcasting tool in an academic course and investigated the tool's degree of acceptance. The survey showed that vodcasting was not just a supporting tool for taking notes but also a medium of study giving options

to interact with the delivered knowledge (Roland, 2013). These results led to the formation of a team of people consisting of teachers, educational designers, developers, researchers, and teachers that acted as the α -testers of the first version of EZplayer that was developed in early 2013. 500 students acted as β -testers and their feedback was used to produce the second bug-free, *responsive-design*, and more interactive version of EZplayer.

A Deeper Look Into EZcast

EZcast is an open source web platform that allows teachers and lecturers to record lectures. Then these recordings can be made available to students via a web media player. Students have access to high quality educational multimedia content consisting not only of recorded audio and video but also by audio-video-synced slide presentations. On the other hand, EZcast allows educational material producers to easily create, edit and distribute it to targeted audience through their web browser. Each user of the platform is assigned a role. The two main roles supported by the platform (i.e., students and instructors) have access to EZplayer, an “*enriched web audiovisual player*” (Roland, 2013). This player has two main features: a set of audio visual handling tools that facilitate the easy transition from an AV stream to an “audio-slideshow” stream and the ability to accelerate or to decelerate a stream, sharing a link in a specific time, etc. In addition, students can add temporal bookmarks to specific frames of a video, thus they are able to tag them with a title, a description, and add keyword fields so to annotate or summarize the lecture that is recorded. Teachers have also the ability to add their own tags but students can modify these teacher-tags. In this way, every student can create lists of “official” and personal tags, which they can be used when performing searches so to retrieve educational material on demand. Moreover, since February 2015, an innovative *discussion function* has been added to the EZplayer. Users can now pinpoint specific framesets of the video thus creating a discussion

Figure 1. A general view of the EZcast Infrastructure
(Jansens & Wijns, 2015)

thread on which everyone can contribute with a comment and then vote for the best replies.

Although it is not our intention to fully describe all the features of each component of the main platform, still it is beneficial for the reader to have a general idea of the platform's infrastructure. Complete documentation, user tutorials, and installation guides concerning EZcast can be found at <http://ezcast.ulb.ac.be/>

Infrastructure

EZcast is a logical application framework composed of five distinct entities: EZrecorder, EZadmin, EZmanager, EZrenderer, and EZplayer (EZcast wiki, 2014). Different users can have access to four web interfaces: EZrecorder, EZadmin, EZmanager, EZplayer. As seen in Figure 1, the five entities interact with each other using

various protocols and links, but main user roles (i.e., instructors and students) mostly interact with EZplayer (i.e., watching, sharing and commenting audiovisual material), and EZrecorder (instructors recording and uploading their videos).

The applications EZadmin, EZmanager, and EZplayer actively communicate with each other so they must be installed on the same server, which

is supposed to run some flavor of UNIX or Linux. EZrecorder allows a user to record videos and publish them to a specific audience by directly communicating with EZmanager. The EZcast framework is freely available as an open source project under LGPL v.3 from 2 git repositories (EZcast² and EZrecorder³).

*Figure 2. Auditorium Hardware Infrastructure
(Jansens & Wijns, 2015)*

An Overview of the Five Entities

EZrecorder allows users to monitor their recordings automatically and autonomously. After a *secure authentication*, lecturers can choose the *album* they want to record, the title of the course, and available streaming formats: Audio-Video, audio-slideshow, or audio-video slideshow. The interface provides full recording management options by giving access to camera controls and predefined scenes. At the end of recording, the sequence can be published directly on the Internet or placed in a private album.

Media files sent to EZrecorder typically have been created in existing auditoriums of the institution equipped with the required hardware infrastructure. As seen in Figure 2, sound captured by a microphone is sent to an amplifier and then to a computer in order to synchronize it with the video. A permanently installed camera sends the captured video to a device that converts it from an analog to a digital format before sending it to the same computer (Mac mini Video). A VGA switch is used so to split the produced slideshows from a lecturer's computer. The output signal is transmitted simultaneously to the auditorium projector and a VGA-to-USB converter before it is fed to another computer (Mac mini Slide).

EZmanager Provides the ability to manage recorded albums, recordings from EzRecorder and submit videos from a user's computer. EzManager offers four modes of content publishing: EZplayer, RSS feeds, direct download, or embed code.

EZplayer This is an online audiovisual player allowing users (teachers and students) to interact directly with educational content. The available options are shown in Figure 2. In particular, transition through various types of streaming, video handlers, visual bookmarks, discussion threads at specific moments of the video, advanced search.

EZrenderer Processes the recordings and video submissions. Users can choose a jingle and titling to be incrustated before the video, and decide on the output aspect ratio and video quality.

EZadmin This is the web interface for users and course administration. For instance, it allows administrators to create new users and courses, add new renderers, enable or disable recorders in classrooms.

SOLUTIONS AND RECOMMENDATIONS

EZcast is a standalone application that must be installed on a server managed by the institution that will eventually run it. Also, it should only be available to targeted audience that belongs to the university in the broad sense of the word. On the other hand, there are ready-to-go educational web tools available to anyone, offering similar player features but with less recording and administrative options. Some of them are as follows:

- TEACHEM (<http://www.teachem.com/>)
- TEACHERS TUBE (<http://www.teacher-tube.com>)
- KHANACADEMY (<https://www.khanacademy.org/>)
- TED (<http://www.ted.com/>), etc.

The tools mentioned above belong to a wide class of tools that are particularly useful for distributing educational content. In addition, most of them offer class management options, student evaluation methods (quizzes, tests, and so on), communication with parents, etc. Even though they are not categorized as vodcasting applications, multimedia content (video, images, slideshows) can be embed or uploaded from educators and learners to the community. In most cases, users passively watch videos through a player with some basic commenting options available. Content-user interactivity features such as commenting on specific moments of the video, quiz questions on the video, and bookmarking framesets for future use, are currently being introduced to some of these applications (Teachem, Khnacademy).

*Figure 3. Basic features of EZplayer
(Jansens & Wijns, 2015)*

FUTURE RESEARCH DIRECTIONS

We have presented the idea of vodcasting, its general use in education, and a particular tool that can be used to create and distribute vodcasts. The next big thing in video is truly interactive video. Currently, some blu-ray movies provide some kind of interactivity. Thus, generating interactive educational videos may be the big thing in educational technology. Naturally, this would demand the creation of video-capturing, editing,

and uploading tools. One more related idea, would be to consider 3D videos, especially videos that describe lab activities.

CONCLUSION

We have presented scientific evidence to support that vodcasting can be beneficial to learners. In particular, they supplement their teaching material nicely. Students become easily quite familiar

with vodcasting tools and seem to give a vote of confidence on their ease of use in addition to their usefulness in their studies. By introducing to vodcasts certain features that are very common to Web 2.0 tools (e.g., some form of interactivity, the ability to comment certain framesets, bookmarking abilities, alteration between vodcasts and podcasts) has turned them into a valuable learning tool. So vodcasting has become the new interactive, note-taking, knowledge acquisition, on demand tool.

EZcast is a new and very promising platform that allows users to create, edit, and upload vodcasts. This tool and other similar tools should be used daily in the educational process.

KEY TERMS AND DEFINITIONS

Educational Technology: Computer software and hardware that is used for educational purposes.

Embed Code: A block of HTML code that is embed in a target page pointing back to the source page and creating relevant content.

LGPL: The *GNU Lesser General Public License* and details how open source software can be freely copied, distributed and modified.

Podcast: An audio file that is posted to some site and which is automatically downloaded by subscribers of the site.

Responsive Design: A web design approach aimed at allowing web content to be viewed properly on all devices, using CSS3 and HTML.

Screencast: A kind of vodcast that consists of screenshots and narrated text.

Secure Authentication: The process of identifying an individual, usually based on a username and password.

Video File Format: A type of file format for storing digital video data on a computer system.

Vodcast: A video file that is posted to some site and which is automatically downloaded by subscribers of the site.

The Vital Importance of Faculty Presence in an Online Learning Environment

Ni Chang

Indiana University – South Bend, USA

INTRODUCTION

One of the instructional methods, which is clamored by students and which could arguably provide high quality educational opportunities, is faculty presence, as it makes possible the interaction between instructor and students and between students and students in a virtual learning environment (O'Reilly, 2009). Online instructors and academic administrators in higher education cannot simply hold an assumption that quality online courses or student learning could largely depend upon good Internet connectivity, high quality equipment, solid content knowledge of instructors (Welch & Napoleon, 2015), and beautifully designed online courses. The presence of an online instructor cannot ever be neglected or marginalized in online students' learning success. Therefore, highly significant is to address roles that instructors play in an online learning environment in order to underscore the crucial importance of faculty presence in the success of student learning.

BACKGROUND

The Paradigm Shift

An ever increasing number of colleges and universities are transferring courses from face-to-face (F2F) classroom meetings to online learning environments, as students seek out different sources for their educational experience (Welch & Napoleon, 2015). More than 6.7 million students

reportedly took at least one online course during the fall semester of 2011, 570,000 more students enrolled themselves in distance education than those in the previous year (Welch & Napoleon, 2015). Recently, more than 60% of administrators primarily in charge of academics at more than 2,800 colleges and universities in the United States made clear that shifting courses from F2F meetings to online was critical to their long-term strategies (Allen & Seaman, 2013).

With the ever expanding online education and given that online instruction differs distinctively from the traditional F2F instruction (Roman, Kelsey, & Lin, 2010), roles that an online instructor play in a virtual learning environment deserve a great deal of attention, as they underline the necessity of teacher presence in an online learning environment.

Hernández et al.'s (2010) study focused on the roles an instructor played in both e- and traditional learning environments. The researchers performed a comparative analysis of students' perceptions with 33 participants involved in a F2F traditional teaching while 23 students engaged in an online environment. Both of the groups taught by the same instructor. Hernández et al found students' perceptions varied regarding the roles that the instructor played in the F2F and online contexts. Generally, F2F group valued the instructor's role in the learning process more highly than the online group. The findings suggest online instructors ought to make additional efforts to better student learning.

reported that students of distance education classes performed poorly and some even were not able to complete online courses. Furthermore,

there seems to have higher dropout rates within online courses than F2F settings, which might be due to a lack of support from instructor and peers and which might be due to students feeling emotionally isolated (Artino & Jones, 2012; Dabbagh & Kitsantas, 2012). The reported findings offer a strong indication that online instructors need to meet the needs of students (Orso & Doolittle, 2012; Welch, Napoleon, Hill, & Rommell, 2014) by playing a variety of roles in online learning classrooms. Hence, in the paradigm shift, a crucial need is to understand roles that online instructors play in a virtual learning environment (Dennen, Darabi, & Smith, 2007) in order to highlight the paramount importance of faculty presence in an online learning environment.

Faculty Presence in Online Learning Environment

Faculty presence originates from. These researchers termed teacher presence as “teaching presence” and explained, “The concept of teaching presence is constitutively defined as having three categories – design and organization, facilitating discourse, and direct instruction” (p. 1). This explanation makes it clear that the presence of an online instructor embraces more than just answering emails and making announcements. With the presence of an online instructor, students would not feel like that they are situated in a “ghost town” (Online Learning Insight, 2012).

According to (O'Reilly (2009)), there are five interaction points, through which online instructors could connect or interact with students. These five interaction points are announcements, email, discussion forums, feedback summaries, and chat sessions. Roles online instructors play through these avenues could also reflect the online instructors' professional teaching dispositions, comprised of instructors' beliefs, values, and attitudes (Welch & Napoleon, 2015).

noted, “[D]ispositions have also been discussed as affective qualities including empathy,” which means that online instructors should make an effort

to know students and to motivate them to learn. Motivation is closely related to students' affect for learning, comprised of students' attitudes, beliefs, and values toward learning (McCroskey, Richmond, & McCroskey, 2006). Students' affective learning is inseparable from teacher presence governed by instructors' beliefs, values, and attitudes.

Students' Affective Learning

Instructors' beliefs, values, and attitudes also affect their verbal and non-verbal immediacy. Verbal immediacy is primarily concerned with ways instructors talk and facilitate student learning in the traditional classroom (Chang, 2011a), whereas nonverbal immediacy involves behaviors that are only observable to receivers or communicators, such as smile, “eye contact, body position, physical proximity, body movement” (Richmond, Gorham, & McCroskey, 1987 in Velez & Cano, 2008, p. 77). Instructor immediacy behaviors communicate positive relational affect (Velez & Cano, 2008): when there exist instructor immediacy behaviors, students feel close to their instructor (Christophel, 1990) and feel motivated to learn (Christophel, 1990; Velez & Cano, 2008). Students have a propensity to take satisfaction responding to questions and actively conceptualize and internalize knowledge (Krathwohl, Bloom, & Masia, 1964).

However, when instructor verbal and non-verbal immediacy are only shown through video lectures, motivation may not be as powerful as when there is an interaction between instructor and student. In a text-based teaching and learning environment, such as discussion asynchronous forums, non-verbal immediacy is non-existent, so is verbal. Then, if instructors are “hiding” from students, a sense of insecurity and overwhelming feeling arises, which could be detrimental to otherwise enthusiastic learning desires.

It is apparent that in an online learning environment, an instructor should make an effort to increase students' affect for learning (McCroskey et al., 2006). noted that learning not only is emo-

tionally oriented, but also cultivated by interacting with other people, in particular, with a course instructor. The presence of an instructor could make happen interactive communication between an instructor and students (Anderson et al., 2001). Therefore, addressing roles that instructors play is extremely necessary, as it could highlight the vital importance of teacher presence in an online learning environment.

MAIN FOCUS: ONLINE INSTRUCTORS' ROLES

Roles instructors play as facilitators for social instruction are critical in creating positive online learning environments and in promoting students' academic engagement (Cho & Cho, 2014) and are vitally important to students' learning satisfaction (Fedynich, Bradley, & Bradley, 2015). In the following text, the roles of an e-instructor are characterized horizontally by two categories: Pedagogical Efficacy, which chiefly focuses on

the promotion of students' cognition (8 roles in total) and Affective Promotion, which largely focuses on the promotion of students' affective learning (19 roles in total). In the category of Pedagogical Efficacy, there are two subtitles, namely, Knowledge Building (5 roles in total) and Instructional Preparation (2 roles in total). In the category of Affective Promotion, there are three subtitles, namely, Purposeful Commitment (9 roles in total), Purposeful Organization (4 roles in total) and Meaningful Management (6 roles in total).

These roles are also set apart vertically across the two categories of Pedagogical Efficacy and Affective Promotion by three distinct stages, namely, Course Development (7 roles in total), Course Delivery (18 roles in total), and Course Completion (2 roles in total) (see Table 1) address these roles one by one, the author will present them in the form of stages in order of Course Development, Course Delivery, and Course Completion. When each of the online instructor's roles is addressed in the following text, one of the subtitles along with the name of that particular role is placed

Table 1. Responsibilities and accountabilities of an E-instructor

Stage	Pedagogical Efficacy		Affective Promotion		
	Knowledge building	Instructional Preparation	Purposeful Commitment	Purposeful Organization	Meaningful Management
Course Development	<i>Inquiry</i>	<i>Decision Making</i>		<i>Course Conversion</i>	
	<i>Practice</i>	<i>Instructional Planning</i>		<i>Constructing</i>	
				<i>Redesigning and Revising</i>	
Course Delivery	<i>Learning Lecturing</i>		<i>Ongoing Assessment Ownership</i>	<i>Receiving</i>	<i>Assisting</i>
	<i>Individualized Instruction</i>		<i>Encouraging</i>		<i>Open Mindedness</i>
			<i>Monitoring Soliciting</i>		<i>Flexibility</i>
			<i>Reminding</i>		<i>Announcement</i>
			<i>Modifying</i>		<i>Acknowledging</i>
			<i>Clarifying</i>		<i>Patience</i>
Course Completion		<i>Informed Decision</i>	<i>Reflective Practice</i>		

in parentheses for easy reading. For example, (Knowledge Building/*Inquiry*) is referred to the role of inquiry an online instructor plays, which appears under Knowledge Building in the category of Pedagogical Efficacy.

COURSE DEVELOPMENT

With respect to teaching presence, according to Anderson et al. (2001), this stage cannot be omitted. During the Course Development stage, in the category of Pedagogical Efficacy, the instructor assumes four roles, ranging from those of gaining technological skills to those of getting the course ready for teaching. That is, the instructor is responsible for acquiring necessary and useful technological skills (Seaton & Schwier, 2014) (Knowledge Building /*Inquiry*) and familiarizes the learned skills through practice (Knowledge Building/*Practice*). During this time, the instructor also needs to engage in research to decide the content of a course plan (Instructional Preparation/*Decision Making*). According to, the role an online instructor plays is to select and filter information for student learning. Carefully determining what information needs to be offered to online students is supported by, who found from interviewing eight e-instructors that the information covered in virtual learning environments was not equivalent to that in F2F settings. One of the interviewees noted, “I went from about 13 individual classes or modules to about six modules” (Wilson et al., 2003). Followed by the decision making, the instructor needs to lay out a course plan appropriate for the students’ learning needs (Chang, 2009b, 2014; Yang & Cornelius, 2005) (Instructional Preparation/*Instructional Planning*). Online instructors need to facilitate well-considered discussion, which ought to be meaningful to students and which can maintain students’ desire for an in-depth study of concepts (Yang & Cornelius, 2005).

During this course preparation stage, students’ affective learning cannot be neglected. An e-instructor plays three roles in this process (Affective Promotion). The online instructor needs to keep in mind that designing an online course is by no means “curriculum conversion” (Roman et al., 2010), because this practice is insufficient to guide students in their acquisition of knowledge in a self-controlled manner (Chang, 2009c) (Purposeful Organization/*Course Conversion*). Learning through a virtual classroom seems intimidating to some and confusing to others. To minimize the degree of apprehension and anxiety, useful are an analysis of the learning environment and offering details of requirements and expectations (Chang, 2011a, 2011b). Such practices are intended to avoid the phenomenon that “an instructional design project may produce a theoretically sound but practically unable product” (Tessmer, 1990, p. 56) (Purposeful Organization/*Constructing*). The unable product could be viewed as a fabulously built online course, but in the end the course might make students feel isolated, frustrated, and intimidated due to a lack of timely and useful assistance (Chang, 2009b, 2014).

O’Reilly (2009) reported that teacher presence reflected through interactive communication between an instructor and students could lead to remove some feelings of disconnect by online students. While instructors are present and interactive, students tend to be encouraged to learn. When an online instructor is present, monitoring students’ learning, autonomy-supportive teaching takes place, which could, in turn, promote students’ motivation and inspire independent and critical thinking (Reeve, 2009). With teacher presence, if a course is repeated in a following semester, an instructor is able to easily engage in modifying *redesigning and revising* the course (Purposeful Organization) (Chang, 2009b, 2014) in hopes to further positive affect student learning. According to, nearly all cognitive oriented teaching and learning is involved with an affective component.

COURSE DELIVERY

It is through the stage of Course Delivery that interactions between an instructor and students vastly transpire. Anderson et al. (2001) found this stage could not be omitted. In other words, this stage should see much interaction between an instructor and students rather than the amount of interaction is minimized, as a great deal of apps and software, such as online video lectures, podcast, etc., is utilized to dominate course instruction.

Specifically, in this stage, the category of Pedagogical Efficacy, an instructor undertakes four roles and works as an academic guide to render needed and useful help to students (Chang, 2011a, 2011b). Along with interacting with students, the instructor needs to play a role of a learner, who continuously and consistently acquires knowledge relating to content areas and to technological skills (Knowledge Building/*Learning*). At the very beginning of this stage, *lecturing* (Knowledge Building/*Lecturing*) students to prepare them for online learning is of essence (Chang, 2009b, 2014; Yang & Cornelius, 2005). During the lecture, the instructor needs to be cautious not to drive students away by making a poor presentation, as some students may feel unsettled by the idea of independent learning (O'Reilly, 2009; Online Learning Insight, 2012). Therefore, needed is a clear elaboration of how to engage in independent study, how to manage one's time, and how to self-regulate one's learning, and how to navigate through an online course as the introduction of a course at the beginning of course delivery.

In the course delivery stage, the online instructor cannot "rest" and let the online course run by itself (Chang, 2011a). Nor can the instructor only conceptualize that his or her responsibility is to respond emails about logistics and/or students' questions. This stage should see teaching presence and social presence, which are expected to bring about cognitive presence (Anderson et al., 2001) and affective learning (Chang, 2011a, 2011b). Communication between an instructor and students plays an important role in shaping students'

views and their approach to learning (Armstrong, 2010). *Individualized instruction* (Knowledge Building) transpires as each communication is tailored to specific needs (Deutsch, 2013). Such practice could work like a fertile ground for individualized instruction, where an instructor could provide students with targeted informational and explanatory feedback (Chang, 2011a, 2011b, 2014; Rhode, 2008), encouraging them to think deeper. This process can provoke students' thinking and provide students with opportunities to advance their learning, by revising and relearning concepts (Chang, 2014; Nicol & Macfarlane-Dick, 2006). The researchers furthered that feedback that was informational and explanatory was low-stakes assessment, helping students see what deficiencies existed in relation to criteria. If receiving useful and meaningful feedback regularly, students can become less uncertain and anxious about their learning than without (O'Reilly, 2009).

The provision of feedback on individual assignments can, in turn, simultaneously provide useful lens for an instructor to know how to further improve the course design and teaching strategies (Chang, 2011a). This kind of interaction with students is *ongoing assessment* (Purposeful Commitment under the category of Affective Promotion), which is essential to high quality teaching and learning. Ongoing assessment allows for providing scaffolding in order to motivate students to construct knowledge. Pivotal is the instructor's appropriate guidance and support, which helps develop students' skills of self-responsibility (Yang & Cornelius, 2005), self-motivation, and a sense of autonomy (Reeve, 2009). These components are all crucial to students' affective learning (Chang, 2011a).

Students' affect for learning during the course delivery stage apparently plays an essential role in the success of their learning. It is thus not surprised to see that an online instructor plays 15 roles in this aspect, which are three times more than those in the Course Development. To cultivate students' affective learning, an e-instructor should be purposefully committed to employing various

strategies to encourage learners to be owners of their own learning (Reeve, 2009) (Purposeful Commitment/*Ownership* and Purposeful Commitment/*Encouraging*). Thus, students may want to actively participate in online discussions and activities (Roberson, 2013). *Monitoring* (Purposeful Commitment) students' learning and then appropriately *assisting* (Purposeful Commitment) them in their learning would help them ease the transition and boost their self-confidence in online learning (Chang et al., 2012). Furthermore, to gradually help students transit from the familiar to the unfamiliar learning environment, the instructor needs to frequently send out email, *reminding* (Purposeful Commitment) students of matters requiring their attention (Chang, 2009b, 2014). In the reciprocal interaction with students, it is fundamental for the instructor to understand that one student's question may be representative of others' and that emerging problems in the process of teaching and learning may become a potent opportunity for the instructor to reexamine the course design and instructional strategies. These can be the basis for the instructor to clarify (Purposeful Commitment/*Clarifying*) topics under discussion and to modify course content as well as ongoing approaches to teaching (Chang, 2009b, 2014) (Purposeful Commitment/*Modifying*).

To further set up an emotionally supportive learning environment, assessments of the effect of course design and delivery are continuous throughout each semester. The instructor purposefully organizes a course by evaluating it based on unexpected email messages and communications with students in various forms such as online discussions, dialogues, and chats. For example, in *receiving* email messages sent by students (Purposeful Organization), an instructor needs to read them carefully, as he or she may be able to learn which assignments are most or least helpful to students. In communicating with students, an instructor could also take advantage of every available opportunity to not only provoke students' thinking, but also solicit students' reactions toward online course delivery or arrangement

(Purposeful Organization/*Soliciting*). Information gained through such a process is conducive to the improvement of instruction.

In interacting with students, it is beneficial for an online instructor to let students know that assistance is readily available to them via email or phone calls (Meaningful Management/*Assisting*). In a geographically isolated learning setting, such an act of an instructor would make e-students feel comfortable, as it demonstrates that the instructor sincerely cares about their online learning (Chang, 2009b, 2014). To support and sustain students' affective learning, the instructor must also maintain an open mind in order to learn about and understand students' needs and learning levels (Meaningful Management/*Open Mindedness*).

During the Course Delivery stage, many unexpected events may occur. It requires the instructor to remain flexible and creative (Meaningful Management/*Flexible and Creative*) to appropriately deal with emergent matters and to promote student learning. In addition, the instructor also needs to utilize emails or Announcement in a course management system (CMS) to inform e-students of class-related information and business that is unrelated to course content (Meaningful Management/*Announcement*).

Giving appropriate and relevant praise could positively encourage and further motivate students to learn (Rhode, 2008). Therefore, the instructor needs to acknowledge the efforts made by students, as the acknowledgement can encourage their continuous endeavors and promote their intrinsic motivation (Meaningful Management/*acknowledging*) (Chang, 2009c). *Patience* plays an important role in online teaching as well (Meaningful Management). Sometimes, an explanation of an assignment needs to be repeated. Sometimes, one concept may require several elaborations. If students fail to understand points embedded in readings, the instructor should ask them to re-read required class materials and/or offer guidance, if needed (Chang, 2009b, 2014).

COURSE COMPLETION

During this stage, an instructor assumes two roles. One is concerned with decision making, which is in the category of Pedagogical Efficacy while the other is self-reflection, which is included in the category of Affective Promotion. Although Anderson et al. (2001) did not include this stage, I believe they are not only essential, but also crucial in the success of online instruction.

The first role is that an online instructor needs to discern and analyze the data collected through the entire semester so that he or she can make decisions about next semester's teaching and learning (*Instructional Preparation/Informed Decision*). The collected data may include students' email, students' feedback about a course, students' survey results, and informal conversations between an instructor and students. These resources may enable the instructor to seek answers to questions of course improvement. Some of these questions may be: What has been achieved in the past semester? What has been viewed as a failure or failures? What lessons should be drawn to improve future online instruction? The instructor answers these questions through *reflective practice* (Purposeful Commitment) to showcase his or her purposeful examination of performance in order to know how to improve instruction.

FUTURE RESEARCH DIRECTIONS

Technology has developed rapidly, so is distance education or e-learning (Margalina, De-Pablos-Heredero, & Botella, 2014). However, alarming is a higher drop-out rate of online learners than that of traditional learners (Rauscher & Cronje, 2005). In order to increase retention rates and to prevent from an increase in online learners' drop-out rate, noted technology should not be the target of blame for poor students' learning. How a course is arranged and designed and how frequently communication takes place between an instructor and students matter more than what technology can

do. Clark (1994) made an analogy: "... media are mere vehicles that deliver instruction, but do not influence learner achievement any more than the truck that delivers our groceries causes changes in our nutrition" (in Rauscher & Cronje, 2005, p. 107). In bringing about students' learning in good quality, online instructors should pay more attention to *how and why* technology is used than to what technology needs to be included in teaching and learning. That is, online instructors should be fully aware of how "to be there" for students while technology delivers a course, as what instructors do or do not do could indeed have an effect on the success or failure of student learning.

One aspect that determines students' learning success or failure is students' motivation to learn. Yet, in a virtual learning environment, the level of students' motivation to learn ought be higher than that in a F2F setting (. Unfortunately, it does not seem the case. ascribed the high dropout rates of e-learners to a lack of motivation. As such, technology alone cannot possibly turn around the situation. It definitely require the presence of an online instructor in a virtual learning environment to employ various strategies to increase students' motivation to learn, which poses pedagogical challenges to online instructors in transitioning from F2F to online settings (Park, Johnson, Vath, Kubiskey, & Fishman, 2013). It is always a challenge for instructors to know how to interact with online learners to build positive relationships with them (Roman et al., 2010). Therefore, it is necessary for colleges and universities to methodically devise a comprehensive plan that can aptly offer quality training and support (Deutsch, 2013; Park et al., 2013) for would-be-e-instructors and online instructors to enhance quality learning (Chang, 2011a; Roman et al., 2010). Good quality training enables online instructors not only to understand online instructional tools, but also develop knowledge as to what they could do to be present and how to attend to students' affective learning. Such training should be a professional development and a prerequisite for success in online teaching (Margalina et al., 2014; Roman et al., 2010). In this

way, faculty can develop knowledge and skills to seriously and carefully attend to students' affective learning (Chang, 2011a). Teaching and learning are not simply about delivering information and/or completing assigned tasks, but they are concerned about students' state of emotion in learning, which leads to their motivation to learn.

CONCLUSION

Online learning isolates learners and the instructor, leaving the community members feeling lonely and, sometimes, frustrated, which could vastly impede teaching and learning. To reduce the level of discomfort, the instructor must be "visible" (Chang, 2009b, 2014) by assuming various roles. Therefore, not only could an instructor promote students' cognition, but also attends to their affective learning. This article addresses the vital importance of faculty present in a virtual learning environment by focusing on various roles that an online instructor should play in an entire process of teaching and learning.

There are eight roles total in the category of Pedagogical Efficacy, which are intended to promote student learning. These roles range from assisting students in gaining technological skills to teaching them academic content. This category also demonstrates that the instructor is responsible for acquiring technological skills and becomes familiar with newly learned skills through practice.

There are 19 roles in the category of Affective Promotion—twice as many roles as in Pedagogical Efficacy. Affective learning has been recognized as more potent and influential than academic efforts in student learning (Rauscher & Cronje, 2005), as students' affective learning is just as critical a dimension of learning as cognition. The roles that an online instructor assumes in this category include interactive communication between an instructor and students, encouragement, acknowledgement, and other logistics. Attending to students' affective learning via every possible

avenue is likely to motivate students to learn and support their cognition, as students' emotions do affect their quality learning (Rauscher & Cronje, 2005); Instructors' scaffolding in a virtual learning environment is also essential to students' success of learning. In short, all these roles require an instructor to be present and visible in an online learning environment, as technology alone cannot promote students affect for learning.

KEY TERMS AND DEFINITIONS

Affective Promotion: Encompasses endeavors and strategies made by an e-instructor in fostering students' emotional involvement in e-learning and in setting up an emotionally supportive learning environment to facilitate student learning.

Instructional Preparation: Is related to avenues in which an e-instructor is engaged to make decisions based on information at hand as well as collected through previous experiences of working with students in order to help plan instruction suited to learners' needs.

Knowledge Building: Refers to an e-instructor, who keeps professionally up-to-date through self-development and learning alongside students and who attains technological knowledge and skills by attending relevant workshops and the frequent interaction with a computer.

Meaningful Management: Refers to an e-instructor who manages a course in ways that may help ease students' unnecessary frustration resulting from their being situated in a novel learning environment. This type of course management

aims to promote students' affective learning in the virtual classroom.

Pedagogical Efficacy: Refers to the growth and development of both faculty and students concerning academics-oriented knowledge and skills ranging from content-specific areas to technological skills through efforts exerted by an e-instructor.

Purposeful Commitment: Refers to an e-instructor who is committed to helping students become owners of their own learning by the instructor becoming visible through various means in the shared virtual classroom in order to support learning.

Purposeful Organization: Refers to an e-instructor who is committed to helping students become owners of their own learning, achieved when the instructor becomes visible through various means in the virtual classroom.

Reflective Practice: Refers to an e-instructor's consistent behaviors in assessing the course by an ongoing, even daily, basis as well as at the end of a semester in order to motivate learners to succeed in learning.

Teacher Presence: Refers to an instructor, who learns new technology, acts as an instructional developer, designs and organizes an online course prior to its commencement, who is there for students, scaffolds and facilitates learning, and promotes students' affect for learning during course delivery, and who evaluates and reflects on his or her performance to modify it for improvement.

Mechanisms of Electrical Conductivity in Carbon Nanotubes and Graphene

E**Rafael Vargas-Bernal***Instituto Tecnológico Superior de Irapuato, Mexico*

INTRODUCTION

In the search for alternative materials to semiconductor materials used commonly in electronics such as silicon, germanium, gallium arsenide, gallium phosphide, etc., researchers around the world have been developing carbon-based materials with ideal electrical properties to operate with high efficiency in nanoelectronics. Carbon nanotubes (CNTs) and graphene represent two technological options for these innovative materials, which can be used either individually, or in composite or hybrid materials as electrical filler. They offer electrical properties such as high electrical conductivity and high dielectric permittivity, which can be tuned by synthesis, doping, functionalization, etc. These qualities can be exploited in applications such as interconnects, electronic devices such as field-effect transistors, batteries, fuel cells, supercapacitors (Yusoff, 2015), electrodes for touch screens (Zheng, 2015), flexible transparent memory circuits, materials for electrostatic discharge (ESD) and electromagnetic interference (EMI) shielding (Vargas-Bernal, 2015c), etc.

This chapter will review the most important electrical transport mechanisms associated with the electrical conductivity of carbon nanotubes and graphene, since these can be used in individual way or within composite or hybrid materials, with the aim of discovering the origin of their extraordinary electrical properties than have been used, are being used, and will be used in diverse technological applications. The effect of a set of technical variables related with electrical behavior of carbon nanotubes and graphene, and associated with the electrical conductivity such as band gap,

intrinsic mobility, percolation threshold, electrical conductivity, and dielectric permittivity, are also discussed.

BACKGROUND

Electrical conduction can be defined as the movement of electrical carriers through a transmission medium. A transmission medium is a material substance that transmits or guides through of itself electromagnetic waves. This movement of carriers generates an electrical current in response to an electrical field. Moreover, in each type of material, different mechanisms of electrical conduction are presented. For example, electrons are electrical carriers in metals, and the Ohm's law is the mathematical relationship used to determine the mathematical expression between the electrical current (I) and the applied potential difference (V) between a pair of ends of the material (Bird, 2014):

$$I = \frac{V}{R} = VG, \quad (1)$$

where R and G are electrical resistance and electrical conductance, respectively. Thus, one or more electrons from each atom can move freely within the metal, since they are loosely bound to the atom in the higher level of the valence band. These electrons are incorporated to the conduction band as electrical carriers due to the potential difference, and therefore, an electrical current is generated. An electrical current is a flow of electrical charge carried out regularly by moving electrons through a medium.

DOI: 10.4018/978-1-5225-2255-3.ch233

Electrical conductivity (σ) also called specific conductance can be defined as the ability of a material for conducting an electrical current. In three-dimensional conductor materials, the electrical conductance can be mathematically expressed as:

$$G = \frac{A}{\rho L} = \frac{Wt}{\rho L} = \frac{Wt\sigma}{L}, \quad (2)$$

where A is the cross-sectional area, L is the length, W is the width, t is the thickness, and, ρ and σ are electrical resistivity and electrical conductivity of the material, respectively. Two different types of electrical conductivities can be found in materials: surface conductivity and bulk conductivity. Surface conductivity or sheet conductance quantifies the electrical conductance of thin films with uniform thickness nominally. This represents the rate between the electrical conductivity of the material, and the thickness of the thin film. Therefore, it is mathematically expressed as:

$$G_s = \frac{t}{\rho} = \sigma t, \quad (3)$$

whose units are square per Ohm or Siemen square or denoted by sq/Ω or $\square/\Omega$ or $\text{S}\cdot\text{sq}$ or $\text{S}\cdot\square$, which is dimensionally equal to an Siemen. Bulk conductance, specific electrical conductance, or volume conductivity (σ) is expressed in units of Siemens per meter (S/m).

Materials can be electrically classified in accordance with their conductivities as conductive, static conductive, or static dissipative (Grady, 2011). The surface conductivity regimes for each are approximately greater than $10^{-4} \text{ sq}/\Omega$, 10^{-6} – $10^{-4} \text{ sq}/\Omega$, and 10^{-12} – $10^{-6} \text{ sq}/\Omega$, respectively. Moreover, the corresponding volume conductivity regimes are > 0.1 , 10^{-3} – 10^{-1} , and 10^{-9} – 10^{-3} S/m . Two applications can be identified in accordance with the value of conductivity: electromagnetic interference (EMI) shielding and electrostatic dissipation (ESD). EMI shielding uses materials with

high conductivity, while ESD requires materials with low conductivity.

In materials such as insulators and semiconductors, there is an energy range called forbidden band or band gap, where electron energy states cannot exist between the top of the valence band and the bottom of the conducting band.

MAIN FOCUS OF THE ARTICLE

Carbon nanotubes and graphene has a structure of conjugated system, where a system of connected p -orbitals with delocalized electrons in atoms, presents alternating single and multiple bonds, which in general may lower the overall energy of the system and increase stability. Two p -orbitals form a π -bond. A π -bond is a covalent chemical bond, where two lobes of one atomic orbital are overlapped to other two lobes of the other atomic orbital involved. Therefore, the π -electrons do not belong to a single bond or atom, but rather to a group of atoms (Jug, 2001). The conjugation can be viewed as the overlap of one p -orbital with another across a sigma bond. A simple model of the energy levels can be considered as a quantum mechanical problem of a one-dimensional particle, representing the movement of a π -electron along a long conjugated chain of carbon atoms as found in carbon nanotubes and/or graphene. In this model, the lowest possible absorption energy corresponds to the energy difference between the highest occupied molecular orbital (HOMO), and the lowest unoccupied molecular orbital (LUMO). Almost all electronic transitions in conjugated π -systems are carried from a bonding molecular orbital (MO) to an antibonding MO (π to π^*), but electrons from non-bonding Lone pairs (pair of valence electrons that are not shared with another atom) can also be promoted to a π -system MO (n to π^*) in charge-transfer complexes. A HOMO to LUMO transition is carried out by an electron if it is allowed by the selection rules for electromagnetic transitions. Thus, the electrical conductivity is guaranteed at using carbon nanotubes and/or

graphene in electronic devices. Carbon nanotubes can achieve electrical conductivities between 100 and 200×10^3 S/m, while graphene can achieve an electrical conductivity between 1,738 S/m and 100×10^6 S/m.

The hexagonal lattice, found in the carbon nanomaterials, possesses the longest mean free path of any known material, in the order of microns. Therefore, a ballistic transport is presented in these materials, since the distance that an electron can travel freely without bumping into anything, or having its path disrupted by scattering is large, which reduces their electrical resistance even at room temperature.

Graphene is an allotrope of carbon, formed by a simple sheet of graphite, which is one-atom thick; with carbon atoms arranged in a regular hexagonal pattern (see Figure 1). It has an extremely low weight, since, a graphene sheet with an area of one square meter; this material only weights 0.77 grams. As a semi-metallic material, this material is a semiconductor, and also it has high electron mobility at room temperature. Graphene has no bandgap, since its conduction and valence bands fulfill the Dirac points. It is possible to induce a

small bandgap in graphene by doping. A material without band gap can convert all wavelengths of light to electrons, with energy levels that even did not found in semiconductor materials, and thus, graphene is a wonderful candidate for use in photovoltaic cells. Graphene has high energy density and/or highest current density (a million times that of copper), that favors the storage capacity and rate of charging/discharging, which make it suitable for batteries and electrical supercapacitors. It has the highest intrinsic mobility (100 times more than silicon) between $15,000 \text{ cm}^2 \cdot \text{V}^{-1} \cdot \text{s}^{-1}$ and $200,000 \text{ cm}^2 \cdot \text{V}^{-1} \cdot \text{s}^{-1}$ nearly unaffected by the temperature (10K and 100K), a fact that hints at defect scattering, being the dominant scattering mechanism (Tanaka, 2014). Graphene has a unique combination of properties that is ideal for next-generation electronics, including mechanical flexibility, high electrical conductivity, and chemical stability.

The graphene presents a very high electrical conductivity, thanks to its zero-overlap semi-metallic behavior, with holes and electrons as charge carriers. The electrons in carbon atoms are distributed in the following way: 2 in the inner shell and 4 in the outer shell. Three outer electrons

Figure 1. Different types of graphene sheets in accordance with their chiral indices (n,m) and chiral angle (ψ)

are connected to other 3 carbon atoms, and the fourth electron is left free to be exploited in the electrical conductivity. These free electrons are called pi (π) electrons and they are located in both sides of the graphene sheet. Moreover, these electrons overlap, and improve the carbon-to-carbon bonds in graphene, leading to electronic properties established by the bonding and anti-bonding, of the orbitals associated with them.

Three different types of sheets of graphene can be identified: armchair, zigzag and chiral, in accordance with the chiral indices, as is illustrated in Figure 1 (Vargas-Bernal, 2015b). Zigzag graphene nanoribbons have a metallic behavior, while armchair graphene nanoribbons can have behavior either metallic or semiconducting. This last depends of the number (N) of atoms across the width where k is the number of nanoribbons presented by the material, and therefore, when $N=3k-1$ a metallic behavior is obtained, if $N=3k$ a semiconducting behavior is presented, and finally, if $N=3k+1$, a moderate semiconducting behavior is achieved (see Figure 2).

Another important parameter which defines the electrical properties of graphene is its bandgap. Graphene has no bandgap, since its conduction and

valence bands fulfill the Dirac points. The Dirac points are six locations in momentum space, on the edge of the Brillouin zone, divided into two non-equivalent sets of three points. The two sets are labeled as K and K' , as is illustrated in Figure 3. Electrons through the graphene propagate according to the tight-binding model (electronic band structure), where they are energetically dispersed as a traveling wave within the medium. The mathematical relationship for determining 2D energy dispersion of the electrons in π bands of graphene is given as (Das, 2015):

$$\varepsilon_{2D} = \pm \gamma_0 \sqrt{1 + 4 \cos \left(\frac{\sqrt{3} k_x a}{2} \right) \cos \left(\frac{k_y a}{2} \right) + 4 \cos^2 \left(\frac{k_y a}{2} \right)} \quad (4)$$

where $\gamma_0 = 3.033$ eV is the nearest-neighbor overlap energy. The ε - k (energy versus wave vector) relationship of the electrical carriers is linear for lowest energies near the six corners of the 2D hexagonal Brillouin zone, which leads to zero effective mass for electrons and holes, as shown in Figure 3 (Shuai, 2012).

Figure 2. Electrical behavior of the graphene related with the number of atoms across the width of the nanoribbon of graphene and the wave vector k

Figure 3. Band structure of graphene (ϵ - k relationship of graphene nanoribbons)

A carbon nanotube is an allotrope of carbon that can be conceptualized as a layer of graphite with one-atom-thick called graphene, which is wrapped as a cylinder. One, two or more layers of graphene can be concentrically wrapped giving place to a single-wall nanotubes (SWNTs), double-wall nanotubes (DWNTs) or multi-wall nanotubes (MWNTs). The wrapping of a graphene sheet can be identified by means of the indices (n, m) , where n and m denote integer numbers representing the number of unit vectors along directions in the honeycomb crystal lattice. When $m = 0$, the carbon nanotubes are called zigzag nanotubes, if $n = m$ they are called armchair nanotubes, and in otherwise, they are called chiral nanotubes, as depicted in Figure 4.

The diameter of an ideal carbon nanotube is determined from its (n, m) chiral indices as:

$$d = \frac{\sqrt{3}a_{CC}}{\pi} \sqrt{n^2 + nm + m^2} \quad (5)$$

where $a_{CC} = 0.142$ nm is the carbon-carbon bond length, as is illustrated in Figure 5. The electrical properties of the carbon nanotubes are directly proportional to the value of the diameter, that is, great values of diameter imply high conductivity and vice versa. The chiral angle is defined as:

Figure 4. Different types of carbon nanotubes according with chiral indices

Armchair Carbon Nanotube

Zigzag Carbon Nanotube

Chiral Carbon Nanotube

Figure 5. Estimation of the diameter of carbon nanotubes according to the chiral indices

$$\psi = \cos^{-1} \left(\frac{2n + m}{2\sqrt{n^2 + nm + m^2}} \right) \quad (6)$$

It allows distinguishing three classes of carbon nanotubes with different electrical properties: armchair ($n=m$, $\psi=30^\circ$) with a metallic behavior, zigzag ($m=0$, $n>0$, $\psi=0^\circ$) with a semiconducting behavior, and chiral ($0<|m|<n$, $0<|\psi|<30^\circ$) with a moderate semiconducting behavior, as shown in Figure 6.

In accordance with Kataura's graph, the band gap energy in a carbon nanotube is inversely proportional to the diameter of the nanotube. In a SWNT, their band gap goes from 0 to 2 eV and their electrical conductivity presents metallic or semiconducting behavior. For a given (n, m) nanotube, when $n = m$, the nanotube has a me-

tallic behavior; if $n-m$ is a multiple of 3, then the nanotube is semiconducting, with a small bandgap, and otherwise the nanotube presents a moderate semiconducting behavior with band gap (Vargas-Bernal, 2012). The chirality has strong influence on electrical properties in nanotubes with small diameter. Theoretically, carbon nanotubes can carry an electrical current density of the order of $4 \times 10^{13} \text{ A/m}^2$, whose value is more than 1,000 times greater than that of metals, such as copper, which reduce the effect of electromigration.

In carbon nanotubes, electrons travel only along the tube's axis, and therefore, these materials are referred to as one-dimensional conductors. At room temperature, the dominant scattering mechanism of transport of electrons implies the emission of optical phonons and it is called ballistic transport. When in a carbon nanotube and graphene nanorib-

Figure 6. Electrical classification of the carbon nanotubes according to the chiral angle and indices

bon, the electrons in transit are not scattered with too many phonons and the devices have about 100 nm long, then the transport of electrons depends on the nanoribbon edge structure and the electron energy. The maximum electrical conductance of a single-walled carbon nanotube is estimated as two times (sheet with two sides) the value than that of a single ballistic quantum channel, that is, $2G_0$ where $G_0 = 2e^2/h$ or $7.748091734625 \times 10^{-5} \text{ S}$, where e is the electrical charge of the electron and h is the Planck's constant. At high temperatures, a different mechanism of transport of electrons is presented in carbon nanotubes called hopping. Hopping is a thermally activated process in which an electron moves from one site to another. The electron loses all information about its phase in the process, and it does not exist, coherence among the amplitudes for finding an electron at different lattice sites.

Electrical transport properties of one-dimensional or quasi-1D nanomaterials such as quantum wires, nanofibers, and carbon nanotubes are been subjected of intense scrutiny with the aim of introducing these materials into electronic applications. Semiconducting carbon nanotubes are used in nano-electronic devices, while metallic carbon nanotubes are applied in nano-interconnects (Das, 2015). The electrical transport in semiconducting carbon nanotubes can be ballistic (tunneling) (see

Figure 7), or diffusive (scattering) (see Figure 8). In carbon nanomaterials, tunneling can be defined as a quantum mechanical phenomenon, where an electron tunnels through or cross a potential energy barrier (space without matter), which it classically could not be surmount. Mechanism of diffusion based on scattering appears when defects, impurities or lattice vibrations are found in the carbon nanomaterials. Diffusion is the movement of electrons from a region of high concentration to a region of low concentration, where variables such as pressure or temperature are involved.

During ballistic transport, carbon nanomaterials do not dissipate heat (Frank, 1998). Electrical conduction in carbon nanomaterials is quantized due to their one-dimensionality, and the number of allowed electronic states is limited. In other words, charge carriers are transmitted through discrete conduction channels without experiencing scattering due to impurities, local defects or lattice vibrations (Vargas-Bernal, 2015a). In addition, the electrons do not find electrical resistance, and no energy dissipation occurs in the conduction channel. For armchair carbon nanotubes, there are two sub-bands that cross the Fermi level, and to semiconducting carbon nanotubes, these sub-bands do not cross the Fermi level. Thus, there are two conducting channels and each band accommodates two electrons of opposite spin (White,

Figure 7. Electrical ballistic transport in carbon nanomaterials

Figure 8. Electrical diffusive transport in carbon nanomaterials

1998). Conduction of electrons in armchair carbon nanotubes experience an effective disorder that is averaged over the tube's circumference, which increases the electron's mean free paths with nanotube's diameter, and therefore, the ballistic transport in the carbon nanotube is guaranteed. The electrical conductivity of individual carbon nanotubes under ballistic conduction achieves the value of 100×10^6 S/m for single-walled and 3.33×10^6 S/m for multi-walled carbon nanotubes, respectively (Li, 2007).

Functionalization of carbon nanomaterials is necessary to interface it with other moieties in order to expand the scope of its electrical/electronic applications (Sreeprasad, 2013). Unfortunately, this also modulates its electrical properties, and therefore, a wide knowledge related with the effect of carrier scattering, carrier concentration, charge polarity, quantum-capacitance enhanced doping, energy levels, transport mechanisms, and orbital hybridization of energy-bands, must be developed. In (Sreeprasad, 2013), the authors have included factors such as covalent bonds, adsorption, π - π bonds, and lattice incorporation to model its influence on electrical characteristics. They discovered that three different mechanisms governing the electrical properties can be identified: (1) conversion of carbon's hybridized state, (2) dipole interactions enhanced via quantum capacitance, and (3) orbital hybridization with an interfacing molecule.

The use of dopants in carbon nanomaterials such as metals increases the electrical conductivity and its electrical current capacity. Ag nanowires have been used to generate hybrid fibers with graphene oxide (Xu, 2013) for applications in high-performance materials, chemical supercapacitors, ultralight aerogels, sensors and catalysts.

Nanocomposites for electrical applications and based on carbon nanotubes or graphene and polymers, must achieve a certain percolation threshold or a minimum volume fraction, to form a cluster of carbon nanotubes or graphene sheets connected, which will operate as electrical pathways, between a pair of electrodes, to carry

out the electrical transport of electrical carriers (Hu, 2014). In this case, the electrical conductivity implies a tunneling of electrons (non-ohmic behavior), one by one, through the polymer found between two neighboring carbon nanotubes or two neighboring graphene nanoribbons.

Carbon nanomaterials can be used as electrical fillers in composite materials or hybrid materials for electronic applications. These materials must be dispersed in polymeric matrix to avoid the formation of agglomerates of fillers. The electrical transport mechanism in these materials is due to tunneling between electrical fillers, since polymers are regularly electrical insulators (Wen, 2012). When aligned carbon nanomaterials are used in a composite material based on polymer (Gong, 2015), anisotropic electrical conductivity in the longitudinal and transverse directions is obtained due to: 1) nanomaterials are distortable, and the Van der Waals forces are presented, and 2) there is structural distortion of the fillers. In addition, aligned graphene in composite materials based on polymers can provide high dielectric constants of over 14000 with 3 wt% of graphene at 1 KHz thanks to the charge accumulation favored by the aligning (Yousefi, 2014).

Surfactants can be used to exfoliate and disperse carbon nanomaterials to be used in composites based in polymers (Mittal, 2015). These additives allow reduce the percolation threshold (minimum percentage to form an interconnected network between electrical fillers), and therefore, a high electrical conductivity is easily achieved, either using high boiling point solvents or low boiling point solvents.

SOLUTIONS AND RECOMMENDATIONS

Different mechanisms are contributing to the electrical conductivity; a complete analysis must be realized to determine the percentage of its influence on electrical properties of the carbon nanomaterials. In real applications, ballistic and diffusive

transports are completely influenced by different perturbations from fabrication and operation of the carbon nanomaterials and their composites or hybrid materials. Models of conductivity electrical must be developed to understand the types of transport presented in aligned carbon nanotubes (Yousefi, 2014; Gong, 2015), segregated structures (Du, 2011), compacted materials composed of multiple carbon nanomaterials (Marinho, 2012), and mixes of graphene and carbon nanotubes in composite and hybrid materials.

Until now, in the case of composite materials, diverse strategies have been proposed to reduce the percentage of the CNTs and/or graphene (electrical fillers) to be incorporated in composites based on polymers or metals with the aim of obtaining extraordinary electrical properties (Min, 2010, Jomaa, 2015). The most critical factor implied in the reduction of the filler is the reduction of the percolation threshold or the minimum value of carbon nanotubes and/or graphene used to achieve the electrical conductivity in composite or hybrid materials. Among these techniques that reduce the quantity of filler used in a composite or a hybrid material, can be mentioned: surfactant treating, acid treating, and chemical functionalization. The surfactants lower the surface tension of carbon nanomaterials, which preventing the formation of aggregates of fillers, and thus, an increasing of electrical conductivity is obtained. The cleaning of carbon nanomaterials by means of acids increases electrical conductivity of them, decreasing the concentration of impure materials found on surface of these materials. However, an excessive time in acid can damage the structure of the fillers. A better dispersion can be achieved with functionalization since it changes the hybridization of the carbon nanomaterials, and thus, electrical properties are also changed.

FUTURE RESEARCH DIRECTIONS

This chapter has presented an overview of the most significant advances in the research on electrical transport mechanism that can be exploited

in carbon nanomaterials such as graphene and carbon nanotubes. More research must be realized to discover the effect of the ambient on electrical conductivity of both carbon nanomaterials as was developed in (Roch, 2015). A lot of work must be realized to model electrical transport in carbon nanomaterials that have been functionalized to be used in electronic applications.

Carbon nanomaterials will continue offering a highly disruptive technology to be exploited in the interconnection of electronic devices, and the fabrication of electronic devices based either in individual elements or as composite and hybrid materials. These materials will be used in the next generation of electrical wires, with the aim of replacing traditional metal ones based on copper or aluminum (Lekawa-Raus, 2014).

CONCLUSION

In this article, different mechanisms involved in the electrical conductivity of carbon nanotubes and graphene, either working individually or within a composite or hybrid materials, have been discussed. In the case of composite or hybrid materials can be distinguished two mechanisms: the formation of a conducting network interconnecting, carbon nanotubes and/or graphene sheets, and the hopping of the electrons within carbon nanomaterials. Carbon nanomaterials can present ballistic transport (perfect material) or diffusive transport (when defects, impurities and lattice vibrations are found). New mechanisms are presented when carbon nanomaterials are functionalized: hybridized states of the carbon atoms, dipole interactions based on quantum capacitance, and orbital hybridization in the interface.

ACKNOWLEDGMENT

This work is part of a project that is being financed by CONACYT-Mexico (project 152524) and supported by PRODEP and ITESI (project 284.15-PD).

KEY TERMS AND DEFINITIONS

Ballistic Conduction: or **Ballistic Transport:** The transport of electrons in a medium having negligible electrical resistivity or the highest electrical conductivity.

Band Gap: An energy difference (in electron volts) between the top of the valence band and the bottom of the conduction band in insulators and semiconductors.

Carbon Nanomaterials: Nanostructures of carbon such as fullerenes, carbon nanotubes, nanofibers and graphene with unique physico-chemical properties with multiple technological applications.

Carbon Nanotubes: Allotropes of carbon with a cylindrical nanostructure of length-to-diameter of up to 132,000,000:1, which have unusual properties and valuable for nanotechnology, electronics, optics and other fields of materials science and technology.

Diffusive Transport: The movement of electrons from a region of high concentration to a region of low concentration where variables such as pressure or temperature are involved.

Electrical Conductivity: The physical property that quantifies how strongly a given material opposes the flow of electrical current. A low resistivity indicates a material that readily allows the movement of electrical charge.

Electronic Device: Device that accomplishes its purpose controlling the flow of electrons applied to digital electronics, analog electronics, microelectronics, optoelectronics, or integrated circuits.

Graphene: A two-dimensional, crystalline allotrope of carbon whose atoms are densely packed in a regular sp^2 -bonded atomic-scale chicken wire (hexagonal) pattern composed by a one-atom thick layer of graphite.

Interconnect: A path of material that connects two elements or components in an integrated circuit, through which electrical current is transported.

Quantum Tunneling or Tunneling: A quantum mechanical phenomenon, where an electron tunnels through a band gap, which it classically could not surmount.

E-Business and Big Data Strategy in Franchising

Ye-Sho Chen

Louisiana State University, USA

INTRODUCTION

Franchising as a global growth strategy is gaining its popularity (Justis and Judd, 2002; Thomas and Seid, 2000; Chen and Justis, 2006). For example, according to the statistics of the China Chainstore & Franchise Association, China has over 4,500 franchises and chain store companies creating more than 5 million jobs nationwide and the country's top 100 franchises generated total sales of \$66 billion with the total number of stores across these 100 franchises at 124,086 (U.S. Commercial Service, 2016). The popularity of franchising continues to increase, as we witness an emergence of a new e-business model, Netchising, which is the combination power of the *Internet* with big data (O'Donnell, 2014; Saunders, 2015; Franchise Update, 2016) for global demand-and-supply processes and the international *franchising* arrangement for local responsiveness (Chen, Justis, and Yang, 2004; Chen, Chen, and Wu, 2006). In his best seller, *Business @ the Speed of Thought*, Bill Gates (1999) wrote: "Information Technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other." (p. 6) Gates' point is quite true when one talks about e-business and big data strategy in franchising. Thus, to see how e-business and big data can be "meaningfully" used in franchising, one needs to know how franchising really works.

BACKGROUND: BUILDING THE FRANCHISOR/FRANCHISEE RELATIONSHIP

Franchising is "a business opportunity by which the owner (producer or distributor) of a service or a trademarked product grants exclusive rights to an individual for the local distribution and/or sale of the service or product, and in return receives a payment or royalty and conformance to quality standards. The individual or business granting the business rights is called the *franchisor*, and the individual or business granted the right to operate in accordance with the chosen method to produce or sell the product or service is called the *franchisee*." (Justis & Judd, 2002, pp. 1-3) Developing a good relationship between the franchisor and the franchisee is the key for a successful franchise (Justis & Judd, 2002). Figure 1 describes how to build a good franchisor/franchisee relationship.

The franchisor needs to learn continuously for the growth of the franchise. The learning process is developed through five stages (Justis and Judd, 2002): (1) Beginner – learning how to do it; (2) Novice – practicing doing it; (3) Advanced – doing it; (4) Master – teaching others to do it; and (5) Professional – becoming the best that you can be. Once reaching the Advanced stage, most preceding struggles have been overcome. However, further challenges will arise as the franchise continues growing. This is especially true once the system reaches the "Professional" stage, where various

Figure 1.

unpredicted and intricate problems could arise. Bud Hadfield (1995), the founder of Kwik Kopy franchise and the International Center of Entrepreneurial Development, aptly stated: “The more the company grows, the more it will be tested.” (p. 156). To capture the learning process, a counter-clockwise round arrow surrounding the franchisor is used to depict the increasing intensity of learning as the franchisor continues to grow.

The franchisee also goes through five stages of franchisee life cycle (Schreuder, Krige, and Parker, 2000): (1) Courting: both the franchisee and the franchisor are eager with the relationship; (2) “We”: the relationship starts to deteriorate, but the franchisee still values the relationship; (3) “Me”: the franchisee starts to question the franchisor that the success so far is purely of his/her own work; (4) Rebel: the franchisee starts to challenge the franchisor; and (5) Renewal: the franchisee realizes the “win-win” solution is to continue working with the franchisor to grow the system. Similar to the franchisor, a counter-clockwise round arrow surrounding the franchisee is used in Figure 1 to depict the increasing intensity as the franchisee continues growing.

As the franchisee progresses through the life cycle, the good relationship gradually develops an influencing process (Justis & Vincent, 2001), depicted in Figure 1 with a bi-directional arrow.

By going through the processes of learning and influencing, supported by big data analytics such as consumer connection (FB, 2014) & boosting engagement (TFO, 2014), picking store locations (Thau, 2014), and tracking franchisee happiness (TFO, 2014), both the franchisor and the franchisee gain the progressive working knowledge of relationship management with the consumers and suppliers. The franchisor, the franchisee, the consumers, and the suppliers in Figure 1 are surrounded with dashed lines, indicating that there is no limit to the learning process.

E-BUSINESS STRATEGY IN FRANCHISING

With the advancement of Internet technology, franchise companies are adapting e-business strategies for perfecting the franchisor/franchisee relationship to grow their franchises globally. Figure 2 is a visual depiction of deploying e-business strategy in franchising. This community of franchise companies, consumers, and suppliers can be virtually connected for relationship management as follows: (1) collaboration with consumers through Internet, enabling the franchisor and the franchisees to build up relationships with customers, prospective customers, investors, competitors, social media,

Figure 2. E-Business Strategy in Franchise Relationship Management

mobile apps, advocacy groups, and government; (2) intra-enterprise collaboration through Intranet, enabling the franchisor to build up relationships with the board of directors, multi-unit franchisees, new franchisees, prospective franchisees, franchisor management and employees; and (3) collaboration with suppliers through Extranet, enabling the franchisor and the franchisees to build up relationships with members and affiliates of international franchise association, law firms, co-branding partners, goods distributors, real estate agents, information systems consultants, accounting firms, and marketing agents.

Harnessing the E-Business Strategy Around the Customer Service Life Cycle

Table 1 shows a customer-service-life-cycle (CSLC) (Ives and Mason, 1990) e-business strategy in franchising (Chen, Chong, and Justis, 2002) for relationship management depicted in Figure 2. Here we define the franchisee as the customer of the franchisor and the franchisee's customer as the customer's customer of the franchisor. The stages of CSLC are based on two well-known

franchising books by Justis and Judd (2002) and Thomas and Seid (2000).

There are four major components in the e-business strategy: (1) Benchmarking the Requirements and Acquisition stages. The CSLC model shown in Table 1 is a comprehensive guide for a franchise to develop its web site, especially at the stages of Requirements and Acquisition. The model may be used to compare a franchise's e-business strategy with its competitors. As the industry progresses, best practices based on the CSLC model will evolve and become a standard for benchmarking and websites enhancements. (2) Helping the franchisees serve their customers in the Ownership stage without the Internet encroachment. There is a rich collection of studies in e-business in franchising (Chen, Chong, and Justis, 2002) showing how the Internet can help the franchisees serve their customers in the Ownership stage, including "Marketing & Promoting the Franchise Products/Services" and "Managing the Franchise System". (3) Cultivating the Ownership and Renewal/Retirement stages with effective knowledge management. As mentioned earlier, the greatest challenge in the Ownership stage is to build up the relationship between the franchisor and franchisee. To cultivate the Owner-

Table 1. The Customer-Service-Life-Cycle (CSLC) E-business strategy in franchising

CSLC	Sub-stages	Internet Strategy	Intranet Strategy	Extranet Strategy
Requirements	Understanding How Franchising Works	Using the web site as the friendly customer relationship management tool to address customer concerns at various stages (Chen, Chong, and Justis, 2002), e.g., providing useful information on financing and showing how the franchise system may help finance the franchise investment Benchmarking and enhancing the web site continuously (Chen, Chong, and Justis, 2002; Chen, Justis, and Chong, 2008), e.g., identifying frequently the best practices of web deign in the industry and improving the web site accordingly	Transforming the organizational structure and corporate culture to fit the e-business operation pushed by the Intranet systems (Zeng, Chen, and Huang, 2008), e.g., designing an environment for more team work opportunities and establishing e-learning environment for the employees	Partnering with suppliers to enhance the various stages of CSLC continuously (Chen, Justis, and Wu, 2006), e.g., a franchise system may need to partner with banks to deliver good services at the stage of “Financing the Franchise Business”. Aligning the Internet and Intranet Strategy with reputable Application Service Providers (ASP) having focused businesses reengineering around the stages of CSLC (Chen, Ford, Justis, and Chong, 2001). For example, Statability.com is a “visionary Web-based Reporting” portal for the hospitality industry. It has the focused business reengineering around the stage of “Managing the Franchise System”. Its focused service is being respected by franchise companies in the hospitality industry, as is evidenced from the ever-increasing list of its client base, including Hilton and Marriott.
	Investigating Franchise Opportunities			
	Obtaining Franchisee Prospectus			
	Making the Choice			
Acquisition	Preparing Business Plan			
	Financing the Franchise Business			
	Signing the Contract			
Ownership	Marketing & Promoting the Franchise Products or Services		Helping the franchisees make sales and serve their customers, e.g., via mobile apps and social media, with proper policies dealing with the Internet encroachment issues	
	Managing the Franchise System		Cultivating the franchisor/ franchisee relationship with effective knowledge management tools (Chen, Chong, Justis, 2000a,b; Chen, Hammerstein, and Justis, 2002; Chen, Seidman, and Justis, 2005), e.g., basic communications support, distance learning, and centralized franchise applications such as employee recruitment and online ordering	
	Building the Relationship between the Franchisor and the Franchisee			
Renewal or Retirement	Becoming a Professional Multi-unit Franchisee or Retiring from the Franchise System			

ship stage so that "Professional" franchisee can advance to the Renewal stage instead of retiring, Chen, Chong, and Justis (2000) suggest building an Intranet-based Franchising Knowledge Repository. The Repository provides a framework based on which a franchise system may transform into a learning organization. (4) Partnering with the

"disruptive technology" providers to enhance the CSLC stages. Innovative entrepreneurs will reengineer their franchise businesses around the CSLC model shown in Table 1. Their ability to track, analyze, and leverage the buying behaviors of their customers in the CSLC sub-stages is their real competitive advantage. For example, Statability.

com is a “visionary Web-based Reporting” portal for the hospitality industry. In terms of the CSLC model, Statability.com is a focused business which reengineers around the sub-stages of Ownership. Its “disruptive technology” of reporting is adopted by many franchises in the hospitality industry. As discussed earlier, partnering with those “disruptive technology” providers will make the franchise system more competitive.

Aligning the CSLC-Based E-Business Strategy with Application Service Providers

Although Internet technology can help deploy the franchise’s e-business strategy, the immediate question is: at what cost? Because of the need for e-business processes to monitor the linkage of internal information technologies with external processing and services, the e-business investment could be very expensive and complicated. Many franchise companies, especially small ones, find it financially difficult to invest in the e-business technologies; however, a new type of service in e-business called Application Service Providers (ASP) promises to make e-business more economical and affordable to the franchise systems. The concept of subscribing information technologies through ASPs has special appeal in the franchising industry because an ASP can duplicate success for other similar franchises quickly and inexpensively (Chen, Ford, Justis, and Chong, 2001). When aligning the CSLC-based e-business strategy with ASPs, a franchise company should focus on (Chen, Ford, Justis, and Chong, 2001): (1) Develop an overall vision of the *applications*, including software and hardware, needed for the company. (2) Determine what applications and the specific *services*, e.g., to be available 24 hours a day and 7 days a week with 99.999% of reliability, you want an ASP to host, which have to be clearly defined in the Service Level Agreement. (3) Evaluate ASP *providers*, i.e., vendors who provide the applications services, using flexibility and trust relationship as the two primary factors.

An Attention-Based Framework for the Franchisee Training

The third industrial revolution, combining information technology with globalization, produces an environment where everyone is facing the problem of information overload. Simon (1971) spoke for us all when he said that ‘a wealth of information creates a poverty of attention.’ (p.41) Getting the franchisee’s attention on training in an information rich world is a major challenge. Ocasio (1997) proposed an attention-based theory of the firm, which allows the firm to shield off irrelevant information and gain access to information relevant to what the firm focuses on. According to Ocasio (1997), attention is defined to “encompass the noticing, encoding, interpreting, and focusing of time and effort by organizational decision-makers on both (a) issues: the available repertoire of categories for making sense of the environment: problems, opportunities, and threats; and (b) answers: the available repertoire of action alternatives: proposals, routines, projects, programs, and procedures.” (p.188) Ocasio (1997) further classifies attention into three principles: (1) focus of attention, what decision makers do primarily depends on the selective issues and answers they focus attention on; (2) situated attention, what decision makers focus on and do depends primarily on the particular contextual environment they are located in; and (3) structural distribution of attention, how decision makers attend to the particular contextual environment they are in depends on how the firm’s attention structure (including rules, resources, and relationships) channels and distributes various issues, answers, and decision makers into specific communications and procedures.

In the context of franchising, what do focus of attention, situated attention, and attention structures look like? How does a franchise design an attention-based training program for the franchisees? We propose an attention-based framework in Table 2 for the franchisee training. Such a framework has two dimensions. The first dimension is the franchisee life cycle, consisting of Beginner

Table 2. An Attention-based framework for the franchisee training

Situating Attention: Relationship Touchpoints		Attention Structures: Demand & Supply Value Networks				
		Customers	Franchisee Outlet	Franchisor Headquarters	Suppliers & Partners	Franchise Community
Franchisee Life Cycle	Beginner in the Courting Phase: Beginner Guide	Focus of Attention: Learning how to become a franchisee ■ Understanding how franchising works ■ Investigating franchise opportunities ■ Obtaining franchisee prospectus ■ Making the choice ■ Preparing business plan ■ Financing the franchised business ■ Signing the contract				
	Novice in the “We”-Phase: Practicing	Focus of Attention: Practicing how to do activities such as: ■ How to get training and services from the headquarters ■ How to find a good site ■ How to find suppliers ■ How to work with the franchisor ■ How to work with fellow franchisees				
	Advanced in the “Me”-Phase: Doing	Focus of Attention: Doing activities such as: ■ How to acquire and keep customers ■ How to hire, train, and fire employees ■ How to manage inventory ■ How to manage the back office operations				
	Master in the Rebel Phase: Teaching Others	Focus of Attention: Teaching others how to do activities such as: ■ How to teach others ■ How to work as team ■ How to do the bulleted processes above for Beginner, Novice, and Advanced franchisees				
	Professional in the Renewal Stage: Creative Learning and Innovation	Focus of Attention: Becoming the best he/she can be by: ■ Learning to creatively improve activities such as: ■ How to cut the cost of the operations ■ How to increase the profit of the operations ■ How to acquire other franchises and brands ■ Looking for opportunities for innovation such as: ■ Are there any new growth opportunities we can create based on our intangible assets of demand & supply value chains? How do we avoid the loss of this new venture? ■ Are there any partnership opportunities with our customers and suppliers so that their customers could become ours and vice versa. ■ What are the major concerns in the communities and how can we help to deal with them and build a good media relationship also?				

in the Courting Phase, Novice in the “We”-Phase, Advanced in the “Me”-Phase, Master in the Rebel Phase (since the rebel ones tend to be those who know the system well and are capable of influencing others to follow them), and Professional in the Renewal Phase. It is vital for relationship building to understand which stage the franchisee is situated and allocate appropriate resources at different touch-points to help them perform their focuses of attention. The second dimension is the demand-and-supply value networks (Chen, Justis, and Wu, 2006), the attention structures of the franchise, consisting of customers, franchisee

outlet, franchisor headquarters, suppliers and partners, and franchise community. The main body of the framework is the focus of attention of the franchise of different levels.

BIG DATA STRATEGY IN FRANCHISING

Leveraging big data for business growth is getting popular in franchising (O'Donnell, 2014; Saunders, 2015; Franchise Update, 2016). Here are some illustrative examples. Franks (2014)

studied Frozen Yogurts' big data practices and suggested empowering users such consumers and franchisees with direct access to the data and let them mix-and-match data and tools to create customized, and creative, analytic sandboxes. van Rijmenam (2015) studied how McDonald's leveraging big data, including using different metrics in their drive-thru system to optimize the customer experience; using predictive analytics to make effective changes in business and people practices; and making organizational changes in their menus, training programs and supply chain. Webster & Hume (2016) offered a framework of touchpoints to maximize the consumer engagements through social media. Kacker & Perrigot (2016) provided some insights on franchise use of the professional social media network LinkedIn.

As shown in Figure 2, Tables 1 and 2, there are many touchpoints of big data within the franchise business community where the franchisor and the franchisee can influence each other. An architecture of big data strategy in franchising is shown in Figure 3. The architecture consists of seven steps of operational process of big data analytics:

1. **Data Generation:** Data of different formats (e.g., numeric, text, audio, and video) may be generated from internal and external sources (Piccoli & Pigni, 2013). Internal data sources include unit operational data, generated during the daily activities at the franchisor headquarters; business legacy data, embedded in the activities that have been working well or gradually adapted since the franchise system came into existence; and social networks data, captured during important franchise meetings such as franchisee training and supplier annual conferences. External data sources include external benchmarking data, used to compare the relationship management activities in the franchise community; and external crowds and networks data, captured from social media such as LinkedIn and used for recruiting prospective franchisees.
2. **Data Integration:** Data of different sources are reconciled and integrated with respect to well-defined formats for easy retrieval. This is a very time consuming process that involves the activities such as recovery, cleansing, extracting, filtering, conditioning, scrubbing, and loading.
3. **Digital Data:** The formatted data is digitalized and stored in the franchise data warehouse with layers of metadata for efficient and effective data administration.
4. **Data Streams:** Digital data is segmented (Pigni, Piccoli & Watson, 2016) according to why it is segmented; where the segment is located; who is the identifier of the segment; what causes the segment to be created; how the event behind the segment is initiated and completed; and when the segment will be activated for value creation.
5. **Data Extraction:** Several data marts are created with data extracted (Piccoli & Pigni, 2015) from the data warehouse based on various franchisee/customer-centered segmentations. Data transformation is needed here that involves the activities such as exploration, replication, propagation, summary, aggregate, and metadata.
6. **Data Harvest:** Data analysis is needed here that involves the use of effective tools such as online analytical processing (OLAP), data mining (Chen, Zhang, & Justis, 2005; Chen, Justis, & Chong, 2008), Adobe Analytics and Predictive Analytics (Aman, 2016).
7. **Value Delivery:** Data harvest producing various relationship performance indicators with strong data visualization capabilities for decision making via decision support systems (DSS).

Figure 3.

FUTURE RESEARCH DIRECTIONS: CYBER SECURITY AND SUSTAINABILITY

There are two future trends necessary for franchises to pay attention to: cyber security and sustainability. Cyber security is the protection of

franchise information systems from damage or theft. It is necessary for the franchisor to incorporate cyber security management in implementing the e-business and big data strategy, e.g., setting up privacy protection policies (Webstersey & Melodia, 2013) and data security risk management (Adler, Demicco & Neiditz, 2015). In responding

to the growing demand for sustainability research and practices, PwC and APICS Foundation (PwC, 2014) surveyed 500 supply chain executives and developed a collaborative framework of sustainable supply chains to help companies prioritize their sustainability strategies. The framework consists of an end-to-end plan identifying environmental, social, economic, and ethical priorities for each of the following five processes: design and plan, source, make, deliver, and use and return. Such a holistic framework, when appropriately implemented, can help develop the franchise socially responsible brands which are important for millennials (Krishnan, et al, 2014).

CONCLUSION

Franchising has been popular as a growth strategy for businesses; it is even more so in today's global and e-commerce world (Chen, Chen, and Wu, 2005) with big data. The essence of franchising lies in managing the good relationship between the franchisor and the franchisee. In this paper we showed e-business and big data strategy plays an important role in growing and nurturing such a good relationship. Specifically, we discussed: (1) managing the franchisor/franchisee relationship through the CSLC approach, where organizational learning is believed to be the key to building the good relationship; (2) harnessing the e-business strategy around the CSLC approach, where four major components are discussed: benchmarking the requirements and acquisition stages, helping the franchisees serve their customers in the ownership stage and avoiding Internet encroachment, cultivating the ownership and renewal/retirement stages with effective knowledge management, and partnering with the "disruptive technology" providers to enhance the CSLC stages continuously; (3) aligning the CSLC-based e-business strategy with application service providers, where trust relationship is the major issue; and (4) leveraging big data to grow the franchise. Two future trends, cyber security and sustainability, were also discussed.

KEY TERMS AND DEFINITIONS

Customer Service Life Cycle: Serving customers based on a process of four stages: Requirements, Acquisition, Ownership, and Retirement. Many companies are using the approach to harness the Internet to serve the customers.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: Courting, “We”, “Me”, Rebel, Renewal.

Franchisee: The individual or business who receives the business rights and pay the royalties for using the rights.

Franchising: A business opportunity based on granting the business rights and collecting royalties in return.

Franchisor/Franchisee Learning Process: The stages of learning, including Beginner, Novice, Advanced, Master, and Professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior.

Franchisor: The individual or business who grants the business rights.

Facilitating Interaction Between Virtual Agents Through Negotiation Over Ontological Representation

Fiona McNeill

Heriot-Watt University, UK

INTRODUCTION

It is universally acknowledged that the problem of integration of information across large communities is a difficult and pressing one, particularly when these communities are disparate, widespread and not under centralised control, such as in the Semantic Web (Berners-Lee et al, 2001). The simplest solution to this problem is the enforcement of a single ontology: a single view of the world. However, if the agents interacting are from different organisations or fields, attempting to use a single ontology is usually neither practical nor desirable. Users need to develop a representation that is best suited to their own problems and they need to maintain and update that representation locally. Even if all users do subscribe to a single ontology, integration problems still exist, as changes and updates are made and users tune their ontologies to fit their own needs.

The problem of ontology matching has been widely studied and powerful solutions are available (see (Shvaiko & Euzenat, 2013; Euzenat & Shvaiko, 2013) for a comprehensive survey. However, the ontologies considered are almost always taxonomies, and the problem of ontology matching is concerned with relating a single term in one ontology to one or more terms in another ontology: for example, a term *car* in one ontology may relate to a term *automobile* or a term *carriage* in another ontology. Much less considered is the problem of relating compound terms such as first-order terms or database entries with multiple fields: for example, a term

car(make,model) in one ontology relating to a term *automobile(model,year,brand)* in another. In such situations we still have the problem of relating the single terms contained within these compound terms – e.g., this matching depends on knowing that *car* may be related to *automobile* and that *make* may be related to *brand*. But we must also consider the overall relation of the compound terms, which requires not only semantic but also structural matching.

Another drawback of traditional ontology matching in an online environment is that it tends to assume full knowledge of all relevant ontologies and is generally performed off-line, prior to interaction. These are the assumptions made by the main evaluation processes for Ontology Matching, such as the Ontology Alignment Evaluation Initiative (OAEI¹). But in large, fast-moving agent communities, or situations where some information may be confidential, we cannot assume that we can have full knowledge of any agent or service we may interact with, nor is it possible to perform the matching off-line if we may not know prior to interaction which agents will need to interact.

In this paper, we introduce our theory of on-the-fly, structured matching and briefly describe the ORS system, which we have developed to implement this theory. Our central hypothesis is that representation – as well as vocabulary and beliefs – must be treated as a fluent and that automated, dynamic matching techniques that can map between structured terms are necessary for full integration of disparate ontologies (Bundy et al, 2006).

BACKGROUND

In a system such as the Semantic Web, where there is no centralised control, we cannot have a complete global overview of the agents and data in the system. Agents may join and leave the system freely and they will all have their own ontologies and data that may be large and complex and may be confidential. We cannot hope for a complete description of the relations between every agent in the system. Our approach is therefore not to consider how such a system can be controlled but how an individual agent can successfully make its way in such a system, interacting with the agents that it needs to interact with, even if these agents are not using the same ontological terms or representations, and even if it is not known in advance of the interaction which agents these will be.

Although many existing ontologies are simple taxonomies, and matching these ontologies is a crucial task, we believe that this kind of matching cannot be sufficient. Agents that are capable of interacting in complex and unpredictable environments need to be able to plan, and planning agents need far richer descriptions of the world: not only taxonomies of classes but also relations and functions between these classes, and planning rules describing how to influence the world. Uniformity of these relations, functions and rules can no more be assumed than uniformity of terms within taxonomies, and therefore matching between these structured objects is just as crucial as the more frequently addressed problem of matching between simple terms within a taxonomy.

Matching large ontologies at run-time, particular ones that contain structured terms, is generally not feasible, but we make this problem tractable by only fixing mismatches when this is demonstrated to be necessary. Since interactions may be frequent and fleeting, there may not be much value in matching the full ontologies, since the interaction that is desired may only require a very small part of the ontologies, and even if inconsistencies exist between the ontologies, these may not lead to communication breakdown between agents during

a particular interaction. Our approach is therefore to diagnose mismatches and refine the ontologies accordingly only when these mismatches directly cause communication breakdown.

To this end, we developed ORS (the Ontology Repair System)². This is a tool that an individual agent (which we name PA – the planning agent) can make use of as an aid when communication breaks down. ORS tracks the course of the communication between PA and any agents it may be interacting with (we name these SA – service-providing agents). If communication proceeds successfully then ORS does not need to be utilised. However, if communication breaks down, ORS begins the diagnostic process, analysing the communication so far and prompting PA to ask further questions in order to pin down a specific mismatch between the ontologies of PA and SA, which is then corrected.

The benefit of ORS is therefore that it allows an agent to interact successfully with other agents, even when their ontologies are mismatched in important ways, and even when this mismatch is between complex, structured ontological objects as well as when this mismatch is between simple terms. It works on the fly and fully automatically even when interactions are unpredictable and unforeseen.

ONTOLOGICAL MISMATCH

Planning agents require ontologies that contain three different kinds of objects, which entail three different kinds of mismatches:

1. Purely semantic mismatch, where the mismatch is between words or phrases – for example, *car* is matched to *auto*: this is the problem that is covered by conventional ontology matching.
2. Structural mismatch, where the mismatch is between structured terms (such as relations and functions) – for example, *car(Make,Model)* is matched to *car(Make)*,

or $car(Make, Model, Year)$ is matched to $car(Make, Model, Date)$.

3. **MISMATCHES** of planning rules, where one agent has a different idea of the conditions and effects of performing an action to another – for example,

```
BuyTicketAction: wants_to_
travel (Me, Destination) → has_
ticket (Me, Destination) matched
to BuyTicketAction: wants_
to_travel (Me, Destination)
and has_money (Me) → has_
ticket (Me, Destination) 3.
```

Of these, the first point is only considered incidentally, due to the large body of work that already addresses this issue; our emphasis is strongly on the second and third points.

Structured Matching

The problem of structural mismatch within ontological mismatch is crucial to successful interaction of agents or services. Not only are the utterances of agents usually structured, but service invocations are also necessarily structured, and their automatic interaction requires structured matching of just the type our work addresses; therefore, semantic matching alone cannot be sufficient.

In our work, we consider quantifier-free, first-order terms; that is, predicates with some number of arguments ≥ 0 . Most common service invocations, such as those expressed in BPEL⁴, as well as most types of database entries, can be expressed in such a way. Our techniques are therefore very widely applicable.

The space of possible mismatches between one first-order term and another, more general, first-order term is described by the theory of abstraction (Giunchiglia and Walsh, 1992). They describe four kinds of mismatch:

- **Propositional Abstraction:** A term is matched to one with fewer arguments – for example, $car(Make, Model)$ maps to $car(Make)$.
- **Predicate Abstraction:** A term is matched to one with a more general predicate – for example, $car(Make)$ maps to $vehicle(Make)$.
- **Domain Abstraction:** A term is matched to one with a more general type of argument – for example, $car(Make, Second-hand-dealer)$ maps to $car(Make, Dealer)$.
- **Precondition Abstraction:** A term is removed from a rule – for example, $has(money, Me) \rightarrow owns(car(Make), Me)$ maps to $has(money, Me) \ \& \ has(id, Me) \rightarrow owns(car(Make), Me)$.

By inverting these relationships, we obtain four dual refinement operators. These abstraction and refinement operations are sufficient for describing most ways in which quantifier-free, first-order terms can be related. Non-identical terms must be either synonymous, more general, less general or unrelated. The case where they are synonymous is dealt with by semantic matching. There are a limited number of attributes of first-order terms: they have predicate names, numbers of arguments, orders of arguments and types of arguments. Variations in these attributes gives the above classification of how first-order terms may be mismatched.

WORKED EXAMPLE

Consider the interaction between a planning agent (PA) which wishes to buy a ticket, and an agent acting as the front-end to a ticket-selling service (the service providing agent – SA). PA contacts SA with the following message:

PA: buy(pa, london, edinburgh)⁵

indicating that PA wishes to buy a ticket between London and Edinburgh. It is likely that SA will have some conditions on selling tickets, for example that the buyer has money, and must verify that these conditions hold. SA will therefore respond with a question:

SA: *money(pa,Amount)?*

This indicates that SA wishes PA to find a suitable instantiation of the variable *Amount* such that the relation *money(pa,Amount)* becomes true. But imagine that PA has money represented as a predicate *money(Agent,Amount,Currency)*, and can instantiate this to *money(pa,100,dollars)*. Perhaps this agent is used to operating in many different currency zones, whereas SA only operates in one currency zone, so their designers chose different representations. This question from the SA is considered a *surprising question* because it does not directly match any of the preconditions in the PA's rule.

PA must therefore respond negatively to SA's enquiry:

PA: *no*

SA: *fail: buy(pa,london,edinburgh)*

However, PA is able to analyse the problem and alter its ontology appropriately. In this instance, it is obvious that the problem is that *money/2* is mismatched to *money/3*. PA can determine that the two arguments of SA's *money/2* match the first two arguments of its *money/3*, and hence the third argument – *Currency* – is redundant. It therefore alters its definition of *money* from *money(Agent,Amount,Currency)* to *money(Agent,Amount)*, and alters all instantiations of this predicate accordingly. This means that it is removing information (that the currency is dollars) that may be important in subsequent interactions. This could be resolved by retaining a copy of the old *money/3*, whilst using the updated *money/2* in the current interaction. Additionally, it is making the assumption that the *Amount* referred to by SA

is in dollars. If the assumption in SA's design that money is in dollars is implicit, it cannot be accessed automatically. Confirmation of this would therefore involve user intervention.

The interaction can then be resumed and this time PA will be able to respond appropriately.

(Note that several important steps, such as discussion of price, have been omitted from this simplified example).

THE ONTOLOGY REPAIR SYSTEM

In this section, we describe the role of ORS through giving a step-by-step description of how it is used by an agent (PA) within a multi-agent, semantic-web-like environment.

1. PA has a goal, or is provided by the user with a goal, and uses its ontology to form a plan to achieve this goal. The steps of this plan will normally involve interaction with other agents. For example, if PA has to organise a journey, it will need to interact with (among others) a ticket-selling agent. Each of PA's planning rules will describe the circumstances under which it believes these other agents (SAs) will perform their roles (e.g., a ticket-selling agent will sell a ticket if it is provided with an appropriate destination and sufficient money). If there are no mismatches, the PA's rule will be compatible with the SA's rule which the SA is actually using to perform the task.
2. In order to achieve the goal, PA will execute each step by communicating with the appropriate SA.
3. PA will request the service it requires from the agent, and then wait for a response. This could be an indication that the service has been performed, but it will usually be further questioning from the SA, which is trying to establish whether or not the preconditions are satisfied, to confirm that it can perform the service.

4. If this process results in the service being successfully performed, PA proceeds to the next step of the plan and the functionality of ORS is not required at this step. However, if failure occurs, PA invokes ORS to attempt to track down the cause of this failure.
5. ORS will analyse all the questioning that has occurred so far, giving particular attention to questions the SA asked that were not expected. Expected questions would tie in with the preconditions of PA's rule for the relevant service; any questions deviating from these, either substantially or through a structural difference, would be a *surprising question (SQ)*. An example from the previous section is the question *money(pa,Amount)?* being asked when the question *money(pa,Amount,dollars)?* was expected; alternatively, a completely unexpected question might be asked.
6. ORS's diagnostic algorithms (briefly described below) use this information, prompting the PA to ask for further information if necessary, to diagnose the problem

and to repair PA's ontology accordingly. Occasionally, the fault can be tracked down to a particular ontological object (in the worst case, the whole rule), but an appropriate fix cannot be found (we know there is a mismatch but do not have enough information to determine exactly what it is). This ontological object is then marked as unusable.

7. PA uses its updated ontology to replan from its current state (so earlier successful plan steps will not be repeated) and the process begins again. This time, it is hoped that the problematic interaction will be more successful, though it may, of course, fail again due to other mismatches, which in their turn must be identified and diagnosed.

FAULT REPAIR AND DIAGNOSIS

The diagnostic process works through a series of algorithms. The flow chart in Figure 1 describes one of these algorithms; this particular flow chart is invoked when the diagnostic process has

Figure 1. Flow chart illustrating part of the diagnostic algorithm

already determined that a precondition of a rule is at fault. This algorithm determines exactly how it is at fault – is it incorrectly named? is one of the arguments wrong? is the number of arguments wrong? When the diagnostic process has narrowed down what kind of mismatch it is, it next needs to determine the details of the mismatch. Predicate, propositional and domain refinement mentioned in Figure 1 all refer to types of mismatches outlined above; the Shapiro algorithm⁶ is used when there is no structural mismatch but an incorrectly instantiated fact. It determines how this incorrect fact came to be believed. Further details of these processes and the other diagnostic algorithms can be found in (McNeill and Bundy, 2007).

NEGOTIATING REPAIRS

The basic version of ORS makes the assumption that only PA makes repairs: if mismatches were found, it was SA's version which was preferred. In practice, however, this may not always be the best option. It may be that making the proposed change would be very costly to PA – for example, it may require changing an ontological object that is frequently used, and changing it may complicate many other interactions, or the proposed change may involve removing detail that is of high value to PA. PA making the diagnosed repair is not the only way to make the interaction possible: SA making the inverse of the repair would also create an understanding between them that would allow the action to be performed. If, in these situations, it was the case that making the inverse change was not costly to SA then the greatest good would be achieved by SA performing the change rather than PA. We refer to this as *maximising social welfare*.

ORS is a system designed to be used by a particular agent and we do not make any assumptions about the agents with which it interacts, so we cannot assume that they also have access to ORS. If they don't then they cannot implement repairs themselves and negotiation is impossible: PA must either perform the repair itself or decline

the interaction. However, in cases where SA does have access to ORS, negotiation is possible.

In order to reflect the idea that there is a greater cost associated with changing some parts of the ontology than others, we have introduced the notion of *protection*. An ontological object that is marked as protected will invoke a higher cost if it needs to be altered than one not. There are two levels of protection - high and low. Protection may be applied to an entire ontological object (e.g., a predicate definition or a rule) or to a part of it (e.g., a particular argument of a predicate or a particular precondition in a rule).

With this extended version of ORS, if PA diagnoses a repair that would lead to the alteration of any protected object, it attempts to negotiate with SA to see if SA would implement the inverse repair instead. Because PA is already providing the mismatch information, SA does not need have access to any diagnostic ability, merely the ability to repair its ontology appropriately. In an open environment, SAs will make such decisions on whatever basis they chose. For the purposes of our implementation, we designed our own SAs which would be prepared to perform the mismatches if they had no relevant protection, and would refuse if they had relevant protection at any level. If SA refuses to perform the inverse repair, PA will make the repair itself if it has only low protection; if it has high protection, it will mark SA as inappropriate and try to re-plan.

We have developed a negotiation protocol through which PA and SA can discuss possible allocations of repairs. The negotiation protocol specifies the set of permissible offers and possible agreements. In addition, it provides the agents with the essential vocabulary and the rules for a successful negotiation. The negotiation outcome - which agent will perform the repair - is always the result of mutual agreement. The strategy that each agent follows is based on a utility-based model: each agent forms its utility for the negotiated repair, and proceeds to negotiate according to this utility. In this way the agents express their preferences. We have also introduced the

notion of an *expert agent*, where if PA and SA are not sure which of their versions is preferable, they can get the advice of an impartial agent. An expert agent can be any agent (other than PA or SA), nominated by either agent, and will be relevant to the particular repair. For example, if the concern is about a predicate representing *money*, a *banking agent* may be consulted.

The lifecycle of negotiation is as follows.

- PA calculates a cost for the repair in the range [0 2]. A cost of zero indicates that no protection is violated, a cost of 1 indicates that low protection is violated and a cost of 2 indicates that high protection is violated.
- PA then calculates the *utility* of repair, which is the cost of the action not being performed less the cost of performing it (currently this is set at 2 for all actions).
- If the cost of repair is higher than zero, PA initiates the negotiation process, sending a suggested repair to SA.
- Once SA receives this, it calculates its own cost and utility scores for implementing this repair. In our current implementation, SAs calculate this score in the same manner as PA; in an open environment, they can choose their own method of calculating it, providing the utility score is in [0 2]. If its utility score is zero, it has no incentive to perform the repair and will send a rejection notice to PA. If its utility score is greater than zero, it will enter into negotiation with PA, sending back a *proposal* for interaction, which contains this utility score.
- PA then calculates the *social welfare* score for either agent performing the repair, where the social welfare of an agreement is a measure of the utility this agreement has for the system in total.
- If the social welfare is maximised by PA performing the repair, it will do so. If the social welfare is maximised by SA performing the repair, PA will request SA to do so. If the social welfare is equal either way then it

is not clear which of the agents should perform the repair (SA can agree or decline). In this situation, the agents may choose to consult an expert agent, which will indicate a preference. It is acceptable for either agent to make the repair. However, since the benefits of the different representations is not clear, we introduce the notion of the *expert agent* to assist in such situations. Both agents have the choice as to whether to accept this recommendation; neither is obliged to recognise the expert agent as an appropriate authority. If both agents do agree to take the expert agent's opinion into account, the utility of the agent with the preferred version is increased by 1, and the negotiation continues on that basis.

In order to make our approach flexible, and applicable to agents in an open environment that have not been designed with this specific interaction in mind, we created an ontology which defines the negotiation protocol, so that this is available to all agents without it being hard-coded into the agent.

1. ORS could refine the mismatch
2. ORS could not refine the mismatch but straightforward improvements to ORS would allow it to solve it.
3. ORS could not refine the mismatch because:
 - a. ORS did not have sufficient functionality;
 - b. This mismatch is outside the current scope of ORS;
 - c. This mismatch is irrelevant to an automated system – this is usually a change to commenting or formatting;
 - d. This mismatch could not occur in the representation ORS currently deals with;
 - e. This mismatch could not be highlighted in a planning context.
4. The information we had about the mismatch was insufficient to determine which category it would fall into.

Figure 2. Piechart illustrating the percentage of mismatches that fall into the following categories⁷

EVALUATION

The standard approach to evaluation of ontology matching, outlined in the OAEI⁸ is to input two full ontologies and evaluate how many of the mismatches between them are correctly or incorrectly diagnosed, or are missed. Such evaluation makes no sense for ORS, since ORS is designed not to discover and patch all mismatches but only those that are impeding interaction. A better metric for ORS, therefore, is to evaluate how frequently it can facilitate interaction that would have failed without access to its functionality.

FUTURE RESEARCH DIRECTIONS

We examined mismatches between several large ontologies and analysed which of these mismatches were described by mismatches ORS could diagnose and refine, and which were not. The pie chart below illustrates the results. Although this highlights that there is much ORS cannot currently do, we believe these results to

be encouraging. This is the first step towards a new approach to ontology mismatch and ORS is a prototype system, so the fact that it can already tackle 38.8% of mismatches bodes well.

Evaluation of the negotiation extension demonstrated that the agents always acted so as to maximise our definition of maximal social welfare. In addition, we used computational tree logic to prove that: deadlock is never reached; when a call for a proposal is received, the receiving agent can always refuse this call or make a proposal; when a proposal is received, the receiving agent can always either refuse it or accept it.

Full details of our evaluation can be found on the ORS website⁹.

CONCLUSION

In this article, we have introduced ORS, a new approach to ontology mismatch which aims to resolve miscommunication between agents, where this occurs due to ontology mismatch. ORS works by diagnosing mismatches and repairing

ontologies during runtime, but only where this is demonstrated to be necessary. ORS is designed to be a tool that an agent interacting in an uncertain world can rely on to assist it when communication breaks down due to misunderstandings.

We have described the kinds of mismatches ORS can diagnose and refine and have briefly outlined promising evaluation results. We have many ideas for increasing the functionality of ORS which should greatly improve these evaluation results, including broadening the scope of the kinds of ontologies ORS can deal with and building in improved semantic matching techniques by incorporating existing semantic matches. Further details of all aspects of ORS, together with full information about our plans for future work, can be found in (McNeill and Bundy, 2007).

KEY TERMS AND DEFINITIONS

Ontology: Formal representation of domain knowledge, containing a class hierarchy and possibly relations and functions between these classes. ORS: Ontology repair system which equips a planning agent to proceed successfully with problematic interaction by identifying and repairing any ontological problems which may have led to the difficulties.

Planning Agent (PA): An agent which responds to goals through forming plans to achieve them and then enacting these plans through interaction within a domain.

Semantic Mismatch: Mismatch between two ontological terms where the structure is the same but the meanings of the words within the terms is not.

Service Providing Agent (SA): An agent which is able to provide a service to a planning agent, providing the correct conditions are met.

Structural Mismatch: Mismatch between two ontological terms where the meanings of the words within the terms is the same but their structure is not (two ontological objects may be mismatched both semantically and structurally).

Structured Ontological Term: An ontological term, such as a relation or function, the meaning of which is determined not only by the meanings of the words in the term but also by their structure.

Surprising Questions: When two agents are communicating with a particular goal in mind, a question that is posed by one agent which is not thought to be pertinent to the situation by the other agent is considered by that agent to be a surprising question.

ENDNOTES

- ¹ <http://oaei.ontologymatching.org/>
- ² <http://dream.inf.ed.ac.uk/projects/dor/>
- ³ Note that the $\rightarrow$ in these rules implies the performance of an action: the predicates on the left-hand side must be true before the action is performed; the predicates on the right hand side are made true after the action is performed.
- ⁴ Web Services Business Process Execution Language Version 2.0, <http://docs.oasis-open.org/wsbpel/2.0/wsbpel-v2.0.pdf>
- ⁵ Note that we use a lower case initial letter to indicate a constant and an upper case initial letter to indicate a variable. In theory, the name of the variable can be anything, but we use the convention of using the type name

so that the type information is immediately apparent. Thus *money(pa,Amount)* indicates that the predicate *money* relates a specific agent named *pa* has an unknown value which must be of type *Amount*.

- ⁶ This is so named as it is loosely inspired by Shapiro's procedure for debugging programs by tracing back to find the original source of the problem.

- ⁷ The differences between these categories and the process by which we determine how to categorise mismatches are not obvious at first glance. Full details of how this categorisation is done can be found on the ORS website (above).

On-Line Credit and Debit Card Processing and Fraud Prevention for E-Business

E

James Williams

University of Pittsburgh, USA

INTRODUCTION

Credit and debit cards are Americans' top choice for online shopping, with 48 percent in 2014 preferring to use credit cards, 30 percent using debit cards and 12 percent using PayPal. (Total System Services, Inc., 2014). With their Visa and MasterCard logos, debit cards look like credit cards, but they do not draw money from the same source as credit cards. Debit cards, sometimes called a check or bank card, draw funds from the user's bank checking account, not a line of credit although prepaid debit cards do not access the user's bank account. Many debit cards are actually dual debit/credit cards. Users can use these dual debit cards as one or the other. If it is used as a debit card, the user must enter the personal identification number (PIN) to authorize the transaction (Velocity Payment services, 2016). The use of EMV (Europay, MasterCard, and Visa) chips on cards has pushed more cyber-criminals to attacking on-line (Card Not Present) for fraudulent purposes.

The 10 largest U.S. merchant acquirers ranked by general purpose transactions tied to PIN- and signature-based debit cards and credit cards accounted for 64.61 billion transactions in 2013 (Federal Trade Commission, 2012). Accepting credit and debit cards is essential for any e-commerce Web site. Processing credit and debit cards over the Internet is one of the fastest growing segments of business transactions. This type of transaction or "card-not-present" transaction requires a special type of merchant account. Also, if someone steals a debit card number, an entire bank account is vulnerable. Although prepaid debit cards are also available (Wikipedia, 2016). Debit cards are

basically processed in the same manner as credit cards (Velocity Payment services, 2016). In the early days of credit and debit card usage, to accept such cards, a merchant needed a merchant account through a bank. But today there are a number of services, generally referred to as credit/debit card processors or merchant account services, which will permit a merchant to accept credit and debit card payments online without their own merchant account. There are actually three different methods for processing credit and debit card payments using a merchant account service. These are:

1. **Real-Time Processing:** Real-time processing allows e-commerce merchants to link their e-commerce shopping cart with a gateway merchant service which will automatically process card payments.
2. **Virtual Terminal (Online Interface):** An e-commerce merchant can also process card transactions, manually, 24 hours a day by logging in online and submitting a secure form through a merchant account interface. A merchant can use this to process card payments while taking the customer's information over the phone if the merchant is able to access the Internet at high speed while talking to the customer.
3. **Automated Recurring Billing (ARB):** Some e-commerce merchant services need to charge customers on a monthly or account threshold basis. Some merchant account services allow the merchant to set the time interval or account threshold level and some services allow a merchant to upload multiple subscriptions using a batch file like Microsoft Excel.

DOI: 10.4018/978-1-5225-2255-3.ch236

PayPal is generally accepted as the most widely used online merchant account service with more than 150 million users across the world. VeriSign operates a competing service called Payflow that is typically used by merchants with a high volume of transactions each month. Although the number of merchant account service providers continues to increase, some of the more popular one are listed below (Smith, 2016; Williams and Premchaiswadi, 2009):

- Flagship Merchant Services
- Gomerchant Merchant Accounts
- Merchant Accounts Express
- Cayan
- Electronic Transfer Inc.
- E-Commerce Exchange
- NorthAmerican Bancard
- Charge.com
- TSYS
- Free AuthNet
- Merchant Credit Card
- Payment Depot
- Helcim
- Transfirst
- Dharma

Companies that sell merchandise and services over the Internet are referred to as e-tailers or e-commerce merchants. These credit and debit card processing services make it easy for e-tailers to start accepting cards for purchases of their products and services.

BACKGROUND

Who Are the Participants in On-Line Credit/Debit Card Purchases?

Consumers and Merchants

The consumer is an individual or organization that has the intent of making a purchase. They have money or credit and they desire goods and

services. The merchant is the one with the goods and services and is looking to sell them to consumers. Consumers are motivated to select a particular merchant by things such as price, service, selection or preference. But the merchant's primary motivation is to make money by selling the goods or services for more money than they paid for them. This money between what they bought it for and what they sold it for is called their margin. There are several different methods to exchange money for products and services such as bartering, cash, checks, debit cards, installment payments or credit cards. When credit and debit cards are used, the consumer and the merchant both have banks that they are working with to process the credit/debit card payment transactions.

Issuing Bank

Consumers typically get their credit/debit cards from a bank or credit union, called the "issuing bank." Sometimes an issuing bank is simply called an "issuer." An issuing bank may not only be associated with major credit card brands such as American Express, MasterCard and Visa, but also with credit cards called "private label credit cards." These are the ones that department stores or shops offer, such as Sears and Target credit cards. Issuing banks are lending institutions that support these credit cards by granting and managing extended credit or maintaining bank accounts for debit cards. The purpose of the issuing bank is to grant a credit or debit card directly to a consumer. The issuer typically has a consumer fill out an application, check the applicant's credit and banking history and maintain their account. The issuing bank is the one that decides what a consumer's credit limit is, based on credit history and current debt load. There are thousands of issuing banks in the United States. In Canada and the United Kingdom as well as most other countries in the world there are far fewer banks. Issuing banks make money on the interest the consumer pays on outstanding balances from previous purchases, and they get a portion of every purchase

a consumer makes with the credit card from a merchant. Debit networks charge an interchange fee that consists of a percentage and a flat transaction fee. Debit networks such as NYCE, STAR and ACCEL maintain computer networks to route transaction information among businesses and banks. A debit network charges an interchange fee and a switch fee to route transaction information over its network. The debit network interchange is very similar in structure and complexity to the interchange fees charged by Visa and MasterCard (Cardfellow, 2016).

Acquiring Bank

The acquiring bank represents the e-commerce merchant. The acquiring bank processes all of the merchant's credit/debit card payments with the associations (American Express, MasterCard, Visa, etc.), and provide the merchant with reconciliation data and other financial tools. The acquiring bank also makes money on every transaction a merchant processes. There are many acquiring banks in the United States and abroad, and merchants are free to move from one acquirer to another. Merchants typically select their acquiring bank based on the amount of money, called basis points, they charge per transaction.

Payment Processors and Gateway Services

Theoretically, e-commerce merchants can connect directly to their acquiring bank, but there are a number of reasons why they may not want, or be able, to do so. There are technical and business requirements for conducting the payment process for credit/debit cards and most merchants don't want to deal with these requirements. As an alternative, they use a third party to process credit/debit card payments for them and their acquiring bank. These third parties are called credit/debit card payment processors and gateway services. Credit/debit card payment processors offer the physical infrastructure for the merchant to com-

municate with the acquiring banks and the credit card associations. They connect all the credit/debit card payment participants together. This permits even very small banks to offer merchant services that they could not provide otherwise. Some credit/debit card payment processors also provide acquiring bank services directly to the merchant.

Gateway services provide merchants physical infrastructure as well. They generally offer technology and integration services among all the participants. The gateway service providers charge the merchant a transaction fee or basis points for their services. These fees are in addition to the credit/debit card payment processor fees the merchant is already paying. If a merchant decides to use a gateway service provider they have to set up accounts with an acquirer. The acquirer can be an acquiring bank or a credit/debit card payment processor that offers acquiring bank services.

Credit Card Associations

The credit card associations such as Visa, MasterCard International, American Express, Discover, etc. are responsible for establishing the procedures and policies for how credit card transactions, services and disputes are handled. They are bound by national banking laws and provide the money that covers some of the fraud that occurs within their membership. Each of the credit card associations operate somewhat differently and even within the same association they may operate differently in different parts of the world.

For example, Visa has regions that operate somewhat autonomously. There is Visa U.S.A., Visa Europe, Visa Asia, etc. Each of these regions has slightly different rules, tools and services. Visa does not actually issue credit cards to consumers; they use issuing banks to issue credit cards that are branded as "Visa." MasterCard International is somewhat different from Visa in that there is one association for the entire world with all regions using the same basic structure, policies, and management procedures. MasterCard International also uses issuing banks to issue credit cards

to consumers that are branded as “MasterCard.” American Express differs by acting as the issuer for all American Express branded credit cards. American Express is one global organization with regional coverage. American Express also differs from Visa and MasterCard in permitting merchants to set up direct connections for performing the acquiring functions.

How the On-line Credit/Debit Card Payment Process Works

When a merchant makes a sale over the internet; the card number, the amount of the sale, and the merchant identification (ID) are transmitted from the merchant’s establishment or the internet Web site over the credit/debit card processor’s computer network. The credit/debit card processor can either be a bank or a merchant account service company called a credit/debit card processor that does nothing but provide credit/debit card processing services as discussed above.

From the credit/debit card processor’s network the transaction is transmitted to the credit/debit card processing company’s computer network. If the customer is using MasterCard, for example, the transaction will go to MasterCard’s computer network. Then, the electronic transaction is sent to the bank that issued the credit/debit card to the customer. The bank’s computer system checks the account and verifies that the customer has adequate funds to cover the purchase. The bank’s computer system then sends the merchant an authorization over these same networks. Although the sale is complete, the transaction is not complete since no actual money has been exchanged.

At the end of the business day the merchant account service (credit/debit card processor) sends that day’s charges to the credit/debit card network, e.g. MasterCard, for processing. The transactions are transmitted via the merchant’s credit/debit card processor service to the credit/debit card network. Individual transactions are then extracted and sent back to the individual cardholders’ banks. The issuing banks then debit the cardholders’ accounts

and make appropriate payments to the merchant’s credit/debit card processor through the Federal Reserve Bank’s Automated Clearing House.

The credit/debit card processor then credits the merchant’s bank account for the transaction amount, minus its fees for the transaction. Those fees are also used for paying transaction fees to the issuing bank and the credit/debit card processing network. Despite the use of computers, it can take two business days before the merchant’s account is credited (Murdock, 2006).

Opening a Merchant Account

In order to accept credit/debit cards, a merchant can open a merchant account with a bank. However, many banks have gotten out of the credit card processing business, and those that remain are often reluctant to service small businesses, particularly ones with limited operating histories. Many small businesses must therefore go through a specialized credit/debit card processor or an independent sales organization, commonly referred to as an “ISO.” Whether a merchant uses a bank, ISO or a credit/debit card processor, they need a merchant account before they can accept credit/debit card payments.

An ISO or an Independent Sales Organization is an entity that acts more or less as a middle man, helping formulate a Bank or Bank/Credit or Debit Card Processor alliance. Within such an arrangement, an ISO has an agreement to sell the services of the Bank or Bank/ Credit Card Processor alliance, and is allowed to mark up the Fees and sign up merchants.

- **Tier I - ISO:** Also known as a Super ISO, Wholesale ISO, Full Liability ISO, and a Full Service ISO, a Tier I - ISO always does their own underwriting and risk-assessment and assumes full chargeback liability for their merchants and provide full technical support.
- **Tier II - ISO:** These are shared liability ISOs. Usually, they do not do their own

underwriting, or require underwriting approval from the ISO or credit card processor with which they are contracted. They provide technical support capabilities and they also have the support from the ISO or credit/debit card processor with which they are contracted.

- **Tier III - ISO:** These are usually comprised of a few salespeople with no technical support to provide to their merchants, Tier III - ISOs also do take any responsibility for any chargeback risk.

Typical Information Required for a Merchant Account

Getting the required information together before applying for a merchant account can save time during the application process. Although different merchant account providers have different requirements typically what follows are required in order to obtain a merchant account:

1. Business checking account
2. A copy of a voided check
3. A copy of the company's Articles of incorporation, business license or reseller license. The purpose of this is to prove the applicant is a legitimate business.
4. Pictures of business office and location
5. Have a web site and URL
6. Photocopy of the merchant's return policy
7. Provide business references
8. Photocopy of recent tax returns
9. Site inspection (pictures of your inventory).
10. A photocopy of the applicant's drivers license (Secondary verification of ID)

Technology Requirements for Processing Credit/Debit Cards on Web Sites

The following are considered to be the technology requirements and best practices for e-commerce Web Sites that accept credit/debit card payments (Federal Trade Commission. (2016).

Create a Secure Payment Web Site

This is needed to protect credit/debit card data and other sensitive information from hackers during the credit/debit card transaction process. Identity theft and credit/debit card fraud are occurring more frequently on the Internet, and merchants must ensure that their customers are protected from internet criminals. Merchants can help secure their site by having a secure socket layer certificate, or SSL. SSL encrypts information being entered on the merchant site as it is sent across the Internet.

Utilize a Compatible Shopping Cart Application

This is required to make sure the merchant's shopping cart application can communicate with the merchant's credit/debit card payment-processing gateway. There are several different types of credit/debit card payment gateways, and each has a set of standards that must be followed. Many of the free shopping cart application software packages do not support all of the available credit/debit card payment gateways. A merchant should check with their merchant account provider or their shopping cart documentation to make sure that all the components will work together. Shopping cart applications fall into two basic categories namely: Local shopping carts that merchants can install on their own Web servers, and third-party shopping carts that run on a provider's web site. If a merchant decides to install his own shopping cart software, he will have a variety of software packages from which to choose. Three popular ones are Miva Merchant, BigCommerce, and Agoracart.

If a merchant would rather not install shopping cart software on his own web site, there are a number of third-party options available. When a merchant utilizes third-party shopping cart software, the merchant must place a link on his web site to the third party's web site where the application exists. This link takes customers to the merchant's offsite shopping cart software.

Provide E-mail Message Encryption

If a merchant plans on accepting orders and sending or receiving credit/debit card information via email, the merchant will need to encrypt the information that is transmitted. PGP, which stands for “Pretty Good Privacy,” is the most common form of email encryption. PGP encrypts an email when it is sent and decrypts the email when it has reached the intended recipient. If e-commerce merchants plan to use PGP, they will also need to make sure that their email clients support it.

Utilize a Firewall

If a merchant stores customer credit/debit card numbers or other personal information on his server, it is necessary to have a site-wide firewall to protect this information.

Use Anti-Virus Software and Update It Often

This will prevent most of the hacker’s attempts to invade the merchant’s Web site and steal personal information such as credit/debit card numbers.

Use Anti-Virus Software

This is another important way to protect the merchant’s network and computer systems from outside intruders.

Regularly Download and Install Security Updates:

ware performance and security can be optimized by installing all service and security updates.

After merchants have implemented these basic technology requirements, they are ready to offer their customers an easy way to purchase their merchandise or services. Merchants can also give their customers comfort in knowing that they are providing a safe and secure method for making credit/debit card payments and providing other personal information.

How Credit/Debit Card Payments are Accepted and Processed Online

If most of a merchant’s business is conducted on the Internet, Real-Time processing is the appropriate solution. When a customer who is using a merchant’s Web site is finished shopping and is ready to pay, typically the customer simply clicks on a “Check Out” button which is a link to a secure page where customers type in their credit/debit card information. After a few seconds, a message will then appear showing whether the credit/debit card has been accepted or declined. Real-Time credit/debit card processor or merchant account service providers will have an online database containing all of the credit/debit card transactions for a merchant which makes month-end accounting and balancing simple. Real-Time processing is the best solution for those who plan on having a high volume of daily transactions. Real-Time processing helps to automate the payment acceptance process, unlike in retail establishments where entering credit card information must be done manually. Most Real-Time solutions are coupled with a “Virtual Terminal” that allows a merchant to process Mail Order/Telephone Order (MOTO) orders manually via a web browser from any location that has access to the Internet.

The process a credit/debit card transaction goes through is fairly complicated; however it generally only takes a few seconds. The steps below illustrate how credit/debit card transactions are typically processed using a Real-Time credit card processing service (Google, 2013):

1. Using the merchant’s shopping cart Web interface, customers select “check out” with the items they placed into their shopping cart or selected from an order form on a merchant’s Website.
2. Customer then selects “credit card” or “debit card” as their method of payment.
3. The customer’s Web browser then connects to the Merchant’s website host’s secure server, and brings up the secure payment form.

4. Customer enter their credit/debit card information on the secure payment form, and authorize the transaction by clicking a “Complete Order” or “Continue” type of button.
5. The credit/debit card transaction information is transmitted to the Website host’s secure server using SSL encryption.
6. The merchant’s secure server connects to the merchant’s processing bank either via a secure payment gateway (a third party which provides the connection to the processing bank), or directly (some credit/debit card processors have their own proprietary secure payment gateway and therefore do not require a third party to provide this service).
7. The credit/debit card processor service sends the transaction to the credit card/debit card processor network, such as Visa, MasterCard, or Flagship Merchant Services and the validity of the card and availability of funds is confirmed.
8. If the credit/debit card transaction is approved, an authorization code is returned to the credit card processor service or to the Secure Payment Gateway from the credit/debit card association network or debit card issuing bank.
9. The authorization is encrypted by the Payment Gateway or credit/debit card processor and transmitted in encrypted form to the secure Web server of the merchant, which permits fulfillment of the order.
10. The merchant’s secure Web server then sends the customer’s Web browser a confirmation receipt.
11. The amount due for the credit/debit card transaction is moved from the card holder’s bank to the merchant’s credit/debit card processing bank. The merchant’s credit/debit card processing bank transfers the money to the merchant’s local bank within 2 to 3 business days.

Figure 1, below, illustrates the technological components of a typical credit card processing system

Minimizing Internet Credit Card Fraud

Although there are no certified global figures on losses from credit/debit card fraud a Nilson Report in July 2015 showed credit card and debit card fraud resulted in losses amounting to \$16.31 billion during 2014. Card issuers and merchants incurred 62% and 38% of those losses, respectively, with the following transactional breakdown: Card issuer losses occur mainly at the point of sale from counterfeit cards while merchant losses occur

Figure 1. Typical credit card processing system

mainly on card-not-present (CNP) transactions on the Web, at a call center or through mail order (The Nilson Report, 2015).

For US buyers, credit card fraud does not pose a significant problem, as their loss is limited to \$50 but debit card fraud can cost a user and financial institutions much more. But for merchants that is not the situation. When a consumer indicates an instance of fraud, the disputed amount is removed from the merchant's account and credited back to the customer. This "chargeback" typically comes with a standard fee of \$15 per instance. At highest risk are downloadable software and entertainment, and high ticket items such as airline tickets, computers, and diamonds.

Payment gateways in the US have developed sophisticated fraud checking, but it has not halted credit/debit card fraud. To protect themselves, merchants can capture IP addresses of purchasers (must inform them that they are doing so), carefully examine purchases made from free e-mail addresses, those with different shipping and billing addresses, bounced e-mail order confirmations, no-existent telephone numbers, and large middle-of-the-night transactions. Merchants must also be cautious about shipping to Eastern European countries with a history of fraudulent transactions and telephone the buyer before shipping high ticket items.

Sophisticated Security Required to Prevent Credit/Debit Card Fraud

Online merchants have been forced to develop sophisticated security protections that far exceed the normal security approval process by the credit/debit card companies (NCR, 2015). Currently, credit card companies only verify whether a credit card number is correct and then match the number against the customer's billing address but the criminals can make sure the number is correct and that the addresses match. Cybercrime in all forms shows no signs of decreasing in the near future. For example, MSNBC reported that Visa quietly informed select merchants that 485,000

credit card numbers were stolen from a major e-tailer in January 1999 and in 2008 Bank of America notified thousand of card holders that their MasterCard information had been compromised. E-tailers (Web Merchants) find themselves in a difficult position regarding credit card fraud (Federal Bureau of Investigation, 2014).

Credit/Debit Card Fraud Solution Approaches

While there does not appear to be any simple solutions, experts believe that potential cyber-criminals will soon begin to reconsider committing credit/debit card fraud. This type of criminal activity has, for a long time, been considered too small to bother with, but using credit/debit cards fraudulently is quickly becoming "identity theft" -- which was recently defined as a serious federal felony. Cyber-criminals do leave digital fingerprints and can get caught. There are a number of approaches used by criminals to commit credit/debit card fraud and there are a number of procedures implemented to deter their attempts at credit/debit card fraud. These are discussed below.

Security Codes

An important Internet security feature that now appears on the back of most Visa/MasterCard and Discover cards, and on the front of American Express cards is a security code. This code is generally a three or four-digit number which provides a cryptographic check of the information embossed on the card. The security code helps validate that the customer placing an online order actually has the credit card in his/her possession, and that the credit/debit card account is legitimate. The security code is only printed on the card and it is not contained in the magnetic stripe information nor does it appear on sales receipts or billing statements. The goal is to make certain that the customer must have the card in his/her possession in order to use this code. Since Card Security Codes are not scanned into standard credit card

readers, in theory, these numbers are only visible to the customer. Visa, MasterCard, Discover and American Express now require Internet commerce sites to obtain the security code for all cards that have a code printed on them. In order for a card transaction to be accepted and processed, this code is required as part of the transaction data.

Unfortunately, the cyber-thieves are also using advanced techniques to ascertain critical information about stolen card numbers. They have developed software that can determine which bank issued a card, harvest the three-digit card verification number and determine the available credit-card limit as well as get personal information such as address and telephone number about the owner.

Credit Card “Skimming”

Criminal gangs recruit individuals who work within restaurants, hotels and retail outlets. The recruits are given battery powered electronic devices known as “skimmers” that read and capture all of the credit or debit card’s details in the few seconds that it takes to swipe the card through the card reader machine. When customers pay their bill, their card is first swiped through the legitimate credit card machine, but then it is also swiped through the “skimmer” reader. The recruits then pass the “skimmer” machines onto counterfeiters, who pay the recruits for their part in the crime. Once the “skimmer” machines have been given to the counterfeiters, they download the information onto a computer and produce a fake clone of the card. The “cloned” card is used to illegally purchase products and services. Skimming is costing card users worldwide millions of dollars in phony charges, as stolen clones are sold and used in the United States and elsewhere around the world. The introduction of EMV chips on credit cards has made the skimming process nearly impossible.

Single Use Credit Card Numbers

Some credit card companies have a new security and privacy offering which utilizes the concept of disposable card numbers. With this system, customers can get unique card numbers linked to their card account each time they make a purchase online. This allows the customer to avoid transmitting their “real” card numbers. The single-use numbers don’t work for recurring charges but they also don’t work for cyber-thieves who try to make multiple purchases

Smart Card Technology for On-Line Purchasing

Newer “smart cards” are embedded with a computer chip containing a digital certificate. A digital certificate consists of basic information about the cardholder’s digital identity. It contains elementary personal information such as the cardholder’s name, e-mail address and digital signature. The digital signature is nothing more than a series of numbers called a public key which forms the basis of encryption algorithms. Unlike a written signature, a digital signature has two purposes. It authenticates who the cardholder is legally and it also allows the cardholder’s messages to be encrypted.

Because the smart card chips are programmable, “smart chip technology” is flexible, and designed for multiple applications. These cards are inserted into a, typically free, smart card reader plugged into the user’s or merchant’s computer. The card, together with a PIN number, allows consumers to buy on the Internet using their digital certificate. The card allows access to an online wallet, which contains information such as shipping and ordering information. This information is automatically transmitted to the merchant’s online order forms.

Address Verification System (AVS)

E-commerce merchants can utilize an Address Verification System (AVS) for consumers from the United States. An AVS takes the consumer's ZIP code and the numbers in the street address, and compares them with the numbers in the card billing address. If they agree, the transaction is authorized; if they do not agree, the transaction is flagged as suspicious or in some cases not allowed, depending upon the merchant's preference. Using AVS lowers the merchant's discount rate, and can protect against stolen cards where the thief has the card number, but not a correct address.

Telephone Number Authentication

A telephone number authentication service can provide a decrease in the number of fraudulent transactions that pass through an on-line e-commerce web site. Most cyber-criminals are not willing to provide their real telephone number to complete a transaction and many, if asked for a telephone number will simply exit the transaction. There are a number of services that will provide real time telephone number authentication. These services can determine whether a telephone number is real, no longer in service, stolen or a legitimate working number at the address given by the user.

Telephone Call Verification

Telephone Call Verification works by automatically calling an online end-user's telephone number at the same time the end-user is making a transaction on a website. The user while on the website answers the phone and is provided a one-time personal identification number (PIN) presented via the web interface; an otherwise anonymous online end-user will be able to confirm that the person who received the phone call and the person who is interacting on the website are the same person.

Customer Transaction and IP History Databases Checks

Another approach for detecting online fraud is to compare a transaction with previous transactions made for a given card number and make sure it fits the pattern of use. There are companies that provide real time checks of cards with databases of millions and, in some cases billions, of records to detect anomalies (Conlin, 2007). This type of service will score a card transaction based on all the intelligence it has gathered both about the transaction and former purchases. In addition, online fraud detection solutions based on a combination of IP reputation analysis and a mutual collaboration network has proved successful. IP reputation uses geo-location and proxy detection by providing relevant information about the IP's historic behavior, both legitimate and suspicious (Wikipedia, 2016).

Intelligent Credit/Debit Card Fraud Detection

An intelligent card detection system monitors card transactions as they occur by gathering data from the current and previous transactions and uses this data to compute a transaction score for the current transaction. The algorithms used to compute such a score are called classifiers. Typically, high scores for transactions are more likely to be fraudulent than low scores thus transaction scores are compared to a threshold and the score is classified as normal or fraudulent. Card fraud detection is a complicated problem involving many input variables such as time, transaction amount, merchant, merchant category code, country, etc. acquired from multiple transactions in a sequence. A classifier computes a fraud score based on a number of these variables.

Two basic approaches have been used in developing classifiers, namely, neural networks and Bayesian decision methods. A neural network is a nonlinear function which takes multiple input

variables and computes a score from them. A neural network consists of a series of interconnected neurons similar to the structure of the brain. The interconnections have weights assigned to them and the input neurons (input nodes) to a network represent each continuous variable and every value that a categorical variable can take. The Bayesian approach to card fraud detection is based on probability theory. Research has identified a number of characteristics derived from card transactions which tend to be predictive of fraud. A Bayesian approach computes the probability distributions for each of these card transaction characteristics using a process called evidence integration to compute a fraud probability from the individual characteristic probabilities (Velocity Payment services, 2016).

Regulatory and Legislative Issues

Management of information risk is now tied to regulatory mandates. Since 1999, laws enacted at the federal and state levels have forced companies to be extremely careful in protecting the confidentiality and reliability of medical, financial and other sensitive information stored on their computer systems. Failure to comply with these mandates can lead to civil and criminal penalties, lawsuits and related litigation costs and, of course, damage to reputations. Although the earlier laws focused on financial and healthcare companies, two of the most recent laws, namely, the 2002 Sarbanes-Oxley Act and the California Data Protection Law (SB 1386), broadened the scope of companies that are required to comply. The Gramm-Leach-Bliley Act (GLB), also known as the Gramm-Leach-Bliley Financial Services Modernization Act, is an Act of the United States Congress that stipulates that every financial institution must protect the security and confidentiality of its customers' personal information. The Federal Trade Commission in conjunction with several other federal and state agencies along with the Federal Bureau of Investigation (FBI) is the

federal agency responsible for enforcement of these laws and mandates.

Federal Trade Commission (FTC)

The FTC deals with issues that are related to the economic life of every American citizen and business. It is the only federal agency with both consumer protection and competition jurisdiction across all sectors of the economy including e-commerce. The FTC is charged with law enforcement and protecting consumers' as well as business' interests by sharing its expertise with federal and state legislatures and U.S. and international government agencies; developing policy and research tools through hearings, workshops, and conferences; and creating practical educational programs for consumers and businesses in a global marketplace with constantly changing technologies (Federal Trade Commission. (2016).

Managing Information Risk

Managing information risk must be integrated with a merchant's overall risk management strategy. The technology infrastructure; including servers, network monitors, and firewalls, needs to be assessed and managed in terms of its relation to people, operations, supply chains and other business drivers. Some of the steps involved with information technology (IT) risk management include paying attention to human factors, putting proper security policies in place, identifying critical assets and fostering better communication and an enterprise-wide perspective among IT managers and risk managers. Bringing together IT, risk management, internal audit, legal and human resources to address information management risk issues produce a consensus to the identification of threats, the areas of operation (ranked in order of most critical and sensitive) that could be affected by a threat, potential financial or reputational loss, and the most cost-effective way to reduce the risk (National Institute of Standards and Technology, 2007).

An Information Risk Assessment

A risk assessment should be performed by any merchant accepting credit or debit card payments and this assessment should examine the following risk factors:

- **System Characteristics:** Assess and identify the resources and information that constitute the systems used for financial purposes and identify the business systems jointly with management personnel, IT personnel and users.
- **Threat Identification:** Conduct interviews and utilize work-group sessions with key management team members, technology administrators and system users to uncover potential threat agents that may impact the confidentiality, integrity and availability of information stored in databases and files.
- **Vulnerability Identification:** Conduct a technical assessment to detect vulnerabilities and to assess how effective the controls are for preventing unauthorized access,
- **Control Analysis:** Assess countermeasures regarding items such as firewalls, encryption, web server access policies, password policies, backup and recovery procedures, change-management procedures, currency of software, hardware maintenance and the physical environment.
- **Insurance Gap Analysis:** Assess current insurance policies in terms of coverage for financial loss arising out of unauthorized access or use of confidential information, damage to third-party software or data as well as damage to the business network or databases and files. The risk assessment can not only help identify the critical areas of risk to be addressed, but can also be used to recommend best practices to remedy the risk.

Credit/Debit Card Fraud Preventive Steps for Online Business Owners

When a merchant physically accepts a credit/debit card, and the charge is authorized, and the merchant has conformed to card regulation, the merchant will get paid, even if a stolen card is used. But, the liability for fraud shifts from the card issuer to the merchant for 'Card Not Present' sales (Internet sales, mail order, and telephone/fax order). After a card processor or registration service approves a card transaction, the merchant should perform additional checks, as fraudulent orders are sometimes approved.

The following methods and techniques (NCR, 2015); (Federal Trade Commission, 2012); (Jepson, (2016) can be utilized to protect an e-commerce merchant against credit/debit card fraud. Typically, a combination of methods is the best approach.

Follow the procedures recommended by your credit/debit card processor and the related card organizations:

- **Authorization Approval:** Make sure you get it from the issuing bank.
- **Address Verification System (AVS):** AVS is only available for the and partially available in four European countries to verify the address matches.
- **Card Verification Methods (CVM):** Security Codes: VISA = CVV2, MasterCard = CVC2, and American Express = CID use a security code of 3 or 4 extra digits, a pin for debit cards.
- **Payer Authentication Programs:** Authentication programs (Verified by Visa and MasterCard's SecureCode) use personal passwords to ensure the identity of the online card user.
- **Real-Time Authorization:** Credit/debit card information is sent to the processor for immediate approval.

- **Bin Check:** The first 6 digits of the credit card are called the Bank Identification Number (BIN).
- **Calling The Card-Issuing Bank:** Call the card-issuing bank, to verify the charge.
- **Different Bill And Ship To Addresses:** Use Google to search for the numeric street address, street name, and zip code.
- **Negative Historical File:** Keep a database of prior fraud attempts, problem customers, charge back records, and customers receiving refunds.
- **Shared Negative Historical File:** Combined negative historical databases by several merchants.
- **Positive Database File:** This file contains a list of good customers.
- **Credit Service Database:** A credit database service, such as Equifax (www.equifax.com), Experian (www.experian.com), and Trans Union (www.tuc.com) are most useful for high-dollar value items.
- **Customizable Merchant Rules:** The merchant sets up rules to stop or flag specific orders for review.
- **Fraud Scoring Systems:** Weights, points or probabilities are assigned for different elements of a transaction (IP Address, free-email account, time of day, AVS results, amount of sale, type of products ordered, shipment method, different shipping/billing addresses, certain zip codes, etc) to generate a fraud score to indicate the likelihood of fraud.
- **Pattern Detection:** Check if multiple orders are placed shipping to the same address, but different credit/debit cards were used. Check orders for an unusually high quantity of a single item.
- **Alternate Thank You Page:** If an order is being shipped to a non-English speaking country, display an alternate thank you page. Require the customer to fax either a photo of the credit card or a Xerox of his/her credit card bill.
- **Custom Built Software:** Some merchants have branded their software, displaying the customer's name in the software.
- **Preventative Data Checking Measures:** Check the data fields to determine if the buyer is a real person. Check if the ZIP Code the customer listed really exists. Check if the customer's e-mail address is formatted properly. Check for incomplete names or an address like 123 Main Street.
- **Free Email Accounts:** There is a much higher incidence of fraud from free email services. Many fraudsters use free email addresses to remain anonymous.
- **Reverse IP Address Checks:** Check if the IP address matches the email address and physical billing address of the customer. The IP address identifies the location of the server where the order was placed. Numerical IP addresses can be checked through programs such as WsPing32.
- **Anonymous and Open Proxy IP Addresses:** IP addresses can also be forged thereby hiding the forged IP address's true location of the fraudster. Organized credit/debit card fraud rings often use anonymous proxies.
- **Checking Telephone Numbers:** The web sites at <http://www.freeality.com/finde.htm>, <http://www.theultimates.com/>, <http://www.anywho.com>, <http://nt.jcsm.com/ziproundacx.asp>, and <http://nt.jcsm.com/ziproundacx.asp> provide tools to match the telephone area code to a postal zip code, reverse telephone directories, search for email addresses, maps, directions, etc. The merchant can call directory assistance to determine if the number on the order phone matches their number.
- **Fax Orders:** When a credit/debit card order is received by fax, require the customer to also fax copies of both sides of the credit/debit card and a copy of their state-issued ID, or driver's license.

- **International Orders:** Some countries have very bad reputations for fraud. Your bank or credit card processor can provide a list of high-risk countries. High risk countries include developing nations like Indonesia, Malaysia, Benin, Nigeria, Pakistan, Israel, Egypt, and Eastern European countries. Placing an international phone call to the issuing bank may make sense for large orders and/or ask the customer to contact the merchant by phone or email for shipping costs. A fraudster may consider this too much contact, and decide to go elsewhere.
- **Calling the Customer:** Calling customers is not only an excellent way to detect fraud, but it can also be a valuable part of your customer service.
- **Web Site Information:** Make sure the order form includes fields to enter the CVV2 verification code imprinted on the card, the name of the card-issuing bank, and the bank's toll-free telephone number, the customer's telephone number and email address.
- **Processing Orders:** Do not ship any order until the charge can be verified by additional checks.
- **Use Temporary Activation Codes:** If the merchant wants to process orders immediately, issue thirty-day temporary validation keys for downloaded software.
- **Anti-Fraud Groups:** Become educated by attending seminars offered by credit/debit card companies and card processors. Organizations such as www.antifraud.com and www.wiscomcomputing.com offer help. These groups also offer tips, databases of stolen credit/debit cards, and web look up tools.
- **File a Complaint With the FTC and the FBI:** If you detect fraud or have been a victim of fraud, file a complaint with the FTC at <https://www.ftccomplaintassistant.gov/> and the FBI's Internet Crime Complaint

Center or IC3, a partnership of the FBI and the National White Collar Crime Center at <http://www.fbi.gov/majcases/fraud/internetschemes.htm>.

FUTURE RESEARCH DIRECTIONS

Machine learning technologies such as artificial intelligence are currently being investigated that can detect and prevent fraud in a variety of financial transactions, including credit cards, debit cards, ATMs, and e-payments. The machine learning system can be built into a client's infrastructure and a machine learning model can be created using existing data and retrained as conditions change, forming an integrated system that allows a client to combat fraud before it happens. By identifying legal transactions that have a high probability of being followed by a fraudulent transaction, an institution can take pro-active measures. While machine learning and stream computing technologies currently can't predict the future, as they continue to be developed they will allow financial institutions to make smarter decisions and work to prevent fraud before it happens.

CONCLUSION

Based on past performance and predictions for the future, it seems safe to say that purchasing goods and services over the internet will continue to increase. This is because it is more efficient for the merchants and they can reach a much larger audience than using the face-to-face, in-store methods of the past. But like most uses of technology, there are individuals who find ways to use the technology for criminal purposes. This has been the case when utilizing credit or debit cards for purchasing goods and services over the internet. Thus, a sort of battleground has evolved between the e-commerce merchants along with their customers and the cyber-criminals. As new technological security methods are implemented by merchants to protect themselves and their cus-

tomers, the cyber-criminals attempt to find ways through or around these technological barriers. If past events are any indication of the future, this battle is not over and merchants and their customers must continue to find secure methods to combat the criminals attempting to fraudulently steal financial and other personal information for their own financial gain.

KEY TERMS AND DEFINITIONS

Acquiring Bank: The bank that represents the e-commerce merchant and processes all of the merchant's credit card payments with the credit card associations.

Credit Card Processor: A third party utilized to process credit card payments for merchants and their acquiring bank.

Credit Card: A card issued by banks, savings and loans, retail stores, and other businesses that can be used to borrow money or buy products and services on credit.

Cyber-Criminal: An individual who commits a crime using a computer and the internet to steal a person's identity such as credit card information.

Debit Card: A bank issued card used for cash transactions, but is not a credit card. In a debit card transaction, the amount of a purchase is withdrawn from the available balance in the cardholder's bank account. If the available funds are insufficient, the transaction is not completed. It is also called asset card in the US.

E-Commerce: The buying and selling of goods and services on the Internet.

Fraud: An act of deception for the purpose of unlawful financial gain using stolen credit card information.

Issuing Bank: The bank that issues consumers their credit cards.

Merchant Account: A legally binding contract wherein an acquiring bank extends a line of credit to a merchant who desires to accept payment using credit cards.

Service Gateway: This is another name for a credit card processor.

Skimming: This is a type of fraud wherein the numbers on a credit card are recorded and transferred to a duplicate card.

SSL: SSL is an abbreviation for Secure Sockets Layer, a protocol developed for transmitting documents over the Internet using a cryptographic system that uses two keys to encrypt data; namely a public key known to everyone and a private or secret key known only to the recipient of the document.

Adoption and Use of Mobile Money Services in Nigeria

Olayinka David-West

Omotayo Muritala

Pan-Atlantic University, Nigeria

INTRODUCTION

The Bill and Melinda Gates Foundation [BMGF] (2013) reports that more than two billion people globally are outside the formal financial sector and are either financially excluded or underserved. Increasing access to quality and affordable financial services accelerates the well-being of households, communities, and economies especially those in the developing world. One promising way to deliver financial services to the poor both profitably and at scale is through digital payment platforms delivered through mobile telephony. With many challenges and difficulties, including infrastructure, policy and regulatory constraints, associated with access to financial services through the bricks and mortar model, driving financial inclusion using mobile money has been considered a veritable approach, especially for rural dwellers.

The Central Bank of Nigeria licensed twenty-one mobile money operators (see Table 1) to provide mobile money services to millions of Nigerians as a means of bridging the gap between the financially served, the underserved and un-served. However, unlike some Kenya where 70% of the population are active mobile money subscribers with just six licensed mobile money operators, Nigeria, with more MMOs has less

than a million (about 0.8%) adult as active mobile money subscribers (EFInA, 2014) indicating low adoption and acceptance of mobile money, most prominent in rural areas where bank penetration is low (Kama & Adigun, 2013, p.33; KPMG, 2015, p.13).

MNOs and financial institutions remain key drivers of mobile services although this is dependent on the licensing and regulatory framework in place. To determine which of these categories is first mover in terms of deployment is largely the dictate of regulatory authorities (Lal & Sachdev, 2015). In Nigeria, MNOs provide voice, data, auxiliary services including mobile payments, in partnership with banks and other third parties. MNOs have the infrastructure and capacity to operate at scale, yet, great challenges to adoption and use of services continue to threaten operations and growth of the sector.

This chapter explored causes of mobile money adoption in Nigeria alongside recommendations to policy makers, mobile money operators, agents and institutions promoting financial inclusion. The state of Nigeria's mobile money services is established through a quantitative analytical approach using data from EFInA's Access to Finance and InterMedia's Financial Inclusion Insight nationwide surveys.

BACKGROUND

Financial Inclusion and Exclusion

Financial inclusion and exclusion have received global attention because of their impacts on development. A common thread to several definitions of financial inclusion (Devlin, 2005; Sarma, 2008; Sarma & Pais, 2011; Demirguc-Kunt & Klapper, 2012; World Bank, 2014; Park & Mercado, 2015; Demirguc-Kunt, Klapper, Singer, & Van Oudheusden, 2015) is its link to ownership of an account with a formal financial institution and the conduct of financial transactions using same account within the last ninety days (Allen et al, 2013; InterMedia, 2015, p.2). Sarma (2008) defines financial inclusion as a process that ensures the ease of access, availability and use of the formal financial system for all members of an economy. Although financial exclusion may be voluntary or involuntary (Park & Mercado, 2015), formal financial services should be readily available and accessible to all. Consequently, Kasproicz and Rhyne (2013) define financial inclusion as a state in which everyone who can use financial services (including disabled, poor, and rural populations), has access to quality financial services at afford-

able prices, in a convenient manner, and with dignity for the clients.

The Global Findex (2014) posited that an inclusive financial system is critical to reducing poverty and achieving inclusive economic growth as getting more people to participate in the financial system opens up potential for business expansion, investment in children's education, ability to absolve financial shocks, combat financial risks associated with individual and business transactions and empowering women economically to have control over their finances. Thus, financial inclusion is critical to inclusive growth as access to finance can enable economic agents to make longer-term consumption and investment decisions, participate in productive activities, and cope with unexpected short-term shocks (Park & Mercado, 2015). Sarma and Pais (2011) proposed an index of financial inclusion that aggregates access, availability and use as measures of a country's financial inclusion standing. Absence of these three key factors is what leads to financial exclusion (Peruta, 2015).

According to EFINA (2014) about 40% of the adult population (18+ years) are excluded (unbanked); about 12% are informally included (under-banked) – using informal financial in-

Figure 1. Financial access status of adult Nigerians

stitutions such as co-operatives, thrifts, money guards, etc.

Intermedia (2015, p.3) reports that two in five Nigerian adults have account with a formal financial institution, accounting for 37% financial inclusion. Although the deep in financial inclusion recorded in 2015 might be explained by the deteriorating security situation due to persistent insurgency (InterMedia, 2015, p.3) and worsening economic situations, Nigeria still faces a daunting task of meeting the 80% financial inclusion target by 2020.

Why Mobile Money?

Peruta (2015) defines mobile money as a financial service that offers electronic accounts (e-wallets) in which customers can deposit, withdraw cash and manage electronic money. Micheni, Lule and Muketha (2013) see mobile money as a technology that uses wireless network infrastructure to facilitate the exchange of money value between various actors involved in a transaction. In contrast to the broad term – digital financial services

(DFS) which refers to financial services provided through an electronic platform such as mobile phones, electronic cards, the internet, etc. (InterMedia, 2015, p.2), mobile money services are built and delivered through mobile phones and mobile telephone networks. Mobile phones are rapidly transforming the way people use and access financial services and while more than a billion people around the world do not have a basic bank account, they do own a cell phone which provides a dramatic opportunity to expand financial access to poor people and achieve financial inclusion (CGAP, 2009a, p.15; 2009b, p.4).

Considered as the most affordable and widely spread technology device around the world, use of mobile phones for mobile money service has challenged traditional methods by creating new, convenient and accessible financial systems (David-West, 2016, p.256) especially in economies where financial regulations are high and do not provide enough room for the poor who may not readily have the requirements to get into the formal financial service stream.

Leveraging on mobile phone penetration opens financial services to millions of people without access to traditional banking services around the world (The Global Findex, 2014; Martinez, Hidalgo & Tuesta, 2013). Mobile money services can be accessed with a non-feature (basic) mobile telephone while leveraging on a robust mobile telephone network spread connecting both rural and urban areas. Zimmerman, Pearse and Bau (2016) opine that mobile money services are a solution to financial insecurity as digitization of cash transfers eliminates the risk of transporting large amounts of banknotes and coins. Furthermore, extra expenses, cash leakage from corruption, barriers of affordability, accessibility (Mbiti & Weil, 2011; Donovan, 2012; and Peruta, 2015, p.5), cost and strict banking requirements such as means of identification are eliminated.

Mobile money is not without opportunities to financial institutions and its operators. CGAP (2009a, p.15) reports that mobile phone banking and other technologies are already dramatically

reducing the costs that banks and microfinance institutions (MFIs) incur in providing financial services to low-income populations. With much lower costs and more convenient services, formal financial services become more attractive to poor people than the informal which are costlier and less secured.

Adoption and Acceptance of Mobile Money

Mobile money services have been in the Nigerian financial market for over 5 years. The InterMedia (2016a, p.1) cross-country comparison report shows that as at 2016, Nigeria has 13 active MMOs, Bangladesh with 2, Indonesia and Pakistan with 8 each, Uganda with 7, while Kenya and Tanzania have 6 mobile money providers each. Only India with 14 has more mobile money providers than Nigeria. However, the adoption of mobile money in Nigeria seems to be the lowest when compared to other countries with fewer numbers of providers despite the 85% mobile telephony penetration (InterMedia, 2016a, p.1).

EFInA (2014) reported that 98.8% of Nigeria's adult population (18+ years) have never used mobile money services while 0.4% have discontinued use of mobile money services. Although about 0.8% are current users as at the time of

the study, only 0.5% representing less than half a million adults Nigerians are registered mobile money users in a country of over 95 million adults.

As at 2015, only about 12% of adult Nigerians were aware of mobile money providers while 13% were aware of mobile money as a concept (InterMedia, 2015a, p.3). Mobile money adoption in Nigeria still remains low and even if the 12% awareness was to be converted to use, only an insignificant 0.3% growth will be recorded (InterMedia, 2015a, p.13). A cursory look at the adoption of mobile money in Nigeria reveals that mobile money is still encased within the banking population. In a nationwide survey conducted by EFInA (2014), it was found that across all financial access strands, about 0.8% users of mobile money (registered and unregistered) are from the banked population.

In 2015, the apex bank estimated the annual mobile money transactions at \$25m, representing 0.005% of total gross domestic product in the period and could be considered low when compared with Uganda where in 2013, mobile money transaction was around \$7.2 billion; \$1.9b in Tanzania and \$7.38b in Kenya, (Ondiege, 2015; Commonwealth, 2014).

Although 36% of Nigerian adults are digitally included, with their registered accounts offering some form of digital access (InterMedia, 2016b,

Figure 2. Mobile money adoption across the adult population

Figure 3. Mobile money use per financial access strand

**This figures are based on EFINA 2014 National Financial Inclusion Study covering 22,044 respondents*

p.19) to financial services, mobile money adoption remains very low. EFINA (2014) reported mobile money access level of 0.8% while Inter-Media (2016b, p.39) reports that in 2015, access to mobile money was 0.9% of which 0.6% are registered users and 0.5% as active users. While the number of mobile money deployments has experienced explosive growth, the number of active mobile money users has not grown on the same trajectory (Davidson & McCarty, 2015, p.2; David-West, 2016, p.257).

Mobile Money Inhibitors

While Nigeria's mobile money market remains saturated with operators in light of other evolving markets and only second to India, low level of adoption and acceptance poses threat to investors and potential users who may be discouraged from adoption and use given the absence of network effects. Understanding causes of low adoption and acceptance is thus instrumental in devising ways of harnessing the potentials of mobile money, not just in Nigeria but also in similar markets facing low adoption and acceptance. Peruta (2015, p.6)

opines that understanding the adoption and assimilation of an innovation such as mobile money is best understudied using models of innovation diffusion, technology acceptance and theory of planned behaviour as they provide theoretical foundation for factors that either promote or inhibit the acceptance and use of a technology.

From existing models, the following factors have been identified as possible inhibitors to mobile money adoption and use:

- **Complexity of Technology:** Technology sophistication has been identified as a hindrance to the adoption and use of a technology/innovation, mobile money inclusive. Models of information systems use such as Davis' (1989) technology acceptance model, Roger's (1995) diffusion of innovation, DeLone and McLean's (2003) IS success model and others confirm the significant relationship between ease of use of a technology and its associated use. Thus, the more complex a technology is perceived to be, the less likely it will be adopted and used. One of the problems associated with non-

adoption/use of mobile money in Nigeria is that many do not understand nor know how the technology works (InterMedia, 2015a, p.17). Davidson and McCarty (2015, p.3) reiterated that most customers do not understand the mechanics of performing transactions and are apprehensive to try something as novel as mobile money. Breaking this barrier requires technology providers designing simple interfaces, simplifying the processes required to initiate and complete a transaction using mobile money services. Increasing complexity of a technology impedes its adoption and use especially when the target users are unskilled and uneducated.

- **Security/Trust:** Shi (2011, p.36) opines that use of mobile financial services is hugely hinged on trust, confidentiality, data integrity, authentication and non-repudiation from the providers. Consequently, MMOs' inability to guarantee these measures translates into poor adoption and use. Trust, integrity and security are integral measures that must be provided if consumers are expected to adopt and use mobile money. When customers do not trust the operator's brand or network, they become hesitant to conduct transactions on such platforms (Davidson & McCarty, 2015, p.2). It should be noted that trust and security are quickly ascertained by intending adopters as they often inquire from peers, friends and family members. This is well documented as social influence under the unified theory of acceptance and use of technology by Venkatesh, *et al* (2003).
- **Education/Financial Literacy:** Davidson and McCarty (2015, p.2) submit that often times customers are aware of mobile money service, but do not understand how it could be beneficial to them. Peruta (2015, p.22) reports that education and financial literacy remain key elements in mobile money adoption as a financial inclusion

instrument. When customers understand mobile money's functionalities and usefulness, they learn how to transact. This typically requires a process of education carried out by an agents, friends or family members (Davidson & McCarty, 2015, p.3). Increasing financial literacy and mobile money adoption can be triggered using mobile agents as instruments of sensitization by playing the dual role of agents and financial educators in their catchment areas (Davidson & McCarty, 2015, p.20).

- **Awareness:** First, when people are unaware of the availability of both financial and mobile money services, adoption and use are usually near zero. Davidson and McCarty (2015, p.3) posit that it is not enough that consumers know the name of the mobile money service or even what mobile money but awareness campaigns must build understanding to help users see how it is both relevant and beneficial to them which is fundamental to their behavioural change towards facilitating adoption and use. Lack of product and service awareness reflects the low level of adoption of mobile money service in Nigeria. From the 2013 survey by NOI Polls, 59% (about 6 out of 10) of Nigerians were completely unaware of the mobile money services while the Ericsson ConsumerLab (2016) reports 42% in the level of mobile money services awareness.

The 2014 financial inclusion survey on Nigeria conducted by EFINA highlights some of the identified inhibitors reported across literature as accounting for the low adoption of mobile money in Nigeria. Figure 4 shows some self-reported inhibitors to mobile money use among those who had previously adopted the innovation but discontinued its use.

While it is true that the technology offers effective, efficient and secured ways of transacting, studies (Micheni *et al*, 2013; Davidson & McCarty, 2015; Peruta, 2015) have not shown that

the technology is without setbacks. One major user self-reported setback to its sustained use is lack of knowledge/understanding of the functionalities and efficient use. About 51% of the early adopters indicated complexity as one of the reasons for discontinuity. Although the technology may not be as sophisticated as it is perceived by early adopters, the level of user education and previous experience with similar technological innovation becomes a factor when it comes to adoption and continuous intention to use (Peruta, 2015; Davidson & McCarty, 2015, p.3).

Other inhibitors to use of mobile money include non-ownership of mobile phones, unavailability of mobile money agents, unstable network, proximity to banking facility, lack of trust, preference for cash and others.

Figure 5 reveals some factors responsible for non-adoption of mobile money services among adult Nigerians who have never used mobile money services.

EFInA (2014) survey reported 87.3% of adult Nigerians as those unaware of mobile money services. Among these, 59.1% lived in rural ar-

eas where majority of the unbanked low-income earners are concentrated.

About 12.1% of non-adoption of mobile money is accounted for by lack of trust in the innovation which is ranked highest among factors that accounted for discontinued use of mobile money. EFInA (2015) *Mobile Money Customer Insights* identified fraud, network and transaction failure, limited number of agents and inadequate infrastructure as challenges experienced by active users of mobile money. Trust is a necessary precondition for trying mobile money and must be high, since for most users, their first interaction with a mobile money service will be to hand over cash to MMOs or their agent representatives (Davidson & McCarty, 2015, p.4). Intending adopters of a technological innovation often inquire from peers, friends and family members who have adopted or had precious/related experience with such technology and once reports relating to trust and security are not satisfactory, intention to use and subsequent adoption are negatively influenced. Davidson and McCarty (2015, p.2) further buttress that as customers lose trust in an operator's brand,

Figure 4. Causes of mobile money use discontinuance

**This figures are based on EFInA 2014 National Financial Inclusion Study covering 22,044 respondents*

Figure 5. Inhibitors of mobile money adoption

**This figures are based on EFINA 2014 National Financial Inclusion Study covering 22,044 respondents*

they are hesitant to conduct financial services on the platform.

Another inhibitor reported by non-adopters is the use of services which do not meet their financial services needs. David-West (2016, p.259) reports that although mobile money schemes offer services such as person-to-person remittances, mobile airtime purchases, utility and retail payments, savings etc., the duplication of services across providers is indicative of either low product innovation capabilities or unmet customer value propositions. Services offered on mobile money platforms must be able to provide customers with more benefits than other alternatives provided through the traditional brick and mortar platform or other digital financial services such as internet banking, ATMs and POS services otherwise, attracting customers remains difficult. Identifying the right customer segment and tailoring financial products that come with better comparative advantage when compared to existing products available to the target market segment is a step in the right direction. Such comparative advantage must be characterised by ubiquitous access, queue avoidance, and alternative payment methods (Shi, 2011, p.56).

Other factors affecting mobile money adoption include unavailability of preferred services

and products, and transaction cost. Although McKay and Pickens (2010) posit that the cost of using mobile money services is about 19% less than charges by banks, putting in perspective that majority (88%) of Nigerians live below \$2.50/day poverty line (Intermedia, 2015a) implies that intending adopters will be put away by the extra service charge.

Drivers of Mobile Money

In driving mobile money adoption, mass sensitization on the availability and customer-tailored services are pre-requisite. Davidson and McCarty (2015, p.3) argue that it is insufficient for consumers to know what mobile money is or the name of various service providers. Awareness campaign must champion the understanding of mobile money in order to influence positive behavioural change towards adoption and use. Costs associated with mobile money use must be less than cost charged by banks. Peruta (2015, p.6) further reports that the growing network of agents and mobile telephone density is an effective bridge to the access gap created by lack of widespread bank branches. GSMA (2012) reports that across 28 countries surveyed, there were more mobile money agents than bank branches. This further highlights the importance

of mobile money to closing financial exclusion gaps. Other drivers of adoption include timely access to financial assets, purchase possibilities irrespective of time and location, and as alternative to cash payments (Shi, 2011, p.34). These are subsumed and elaborated below:

- **Transaction Cost:** Micheni, *et al.* (2013) posit that transaction cost negatively influences adoption of mobile money and if cost is affordable and acceptable, there would be ease of adoption and use. However, cost is relative to the target market segment under consideration. When mobile money is deployed as a tool for financial inclusion, the target market segment is predominantly the rural poor who are unemployed, low education, financially illiterate and unwilling to incur cost on the simplest form of transaction – if possible, will appreciate such innovation to come free of charge.
- **Facilitating Conditions:** These refer to the organisational and technical resources and capabilities deployed to support users' exploitation of a system. Beyond providing infrastructural and technical support for customers to optimize the use of a system/technology, facilitating conditions also include support such as incentives, training/sensitizations, and customer support offered by technology and service providers to facilitate the adoption and use of a product or service – in this case, *mobile money*.
- **Comparative Advantage:** Many customers are not technologically confident, with low level of financial literacy (Micheni, *et al.*, 2013), unbanked with irregular or low income and often lack access to formal financial channels who in their vulnerability would readily trust mobile money providers to manage their money. Consequently, they want to stay close to their monies – which can be best provided for them in the form of facilitating conditions that offer them easy and fast access to their money.
- **Compatibility:** Shi (2011, p.35) reports that the compatibility of mobile payments with consumers' purchase transactions, habits, and preferences correspondingly influence further adoption and diffusion of mobile money. For mobile money systems to be adopted and used, consumers must be able to integrate such payment systems into their daily life which is an important aspect of compatibility.
- **Perceived Usefulness:** Across information systems research, the usefulness of a technology in meeting user needs is considered as a pre-condition for adoption, diffusion and use. Researchers in financial inclusion studies consider this as value proposition that the provider must clearly define in order to convince users of the need to adopt and use an innovation. David-West (2016, p.262) emphasised that the statement of access to the equivalency with cash in the mobile money space summarises customer value proposition. When value proposition is not clearly defined, perceived usefulness may be elusive, and adoption hindered.
- **Accessibility:** With liberalisation of the telecommunications sector, mobile telephony adoption has overcome socio-economic barriers to exceed banking penetration in under a decade (David-West, 2016, p.257). The delivery of financial services through this platform provides wider reach to millions of customers with access to mobile phones. Ubiquity of mobile money services is among several benefits that consumers expect to harness which further accelerates adoption and diffusion. This is likened to comparative advantage of Roger's (1995) diffusion of innovation theory. Thus, consumers must be able to see the relative advantage of mobile money over traditional and/or other form of banking services for adoption and use the technology.

Supporting Evidence From Available Data

From the EFINA (2014) data, evidence of perceived drivers of mobile money adoption are illustrated in Figure 6.

Users self reported benefits of mobile money services provide insights into its comparative advantage in deepening financial inclusion as compared to the brick and mortar banking. Fast and ease of transacting, social influence and safety and being alternative saving platform as shown in Figure 6 are reasons users remained committed to using mobile money. Although social influence

accounts for about 30%, the profile of the financially excluded - rural, low income, female, low education, unemployed and youthfulness (ages 18–35) combined to make the use of mobile money a viable tool for both domestic and international remittances amongst others especially in places where access and availability of traditional banking infrastructure is lacking.

About 38.7% of unregistered mobile money users would likely consider adoption once they have understanding of how it works, assured of safe transaction, proximity of mobile money agents, and mobile money attaining critical mass.

Figure 6. Reasons for use mobile money services

Mobile Money Adoption: Far-Striking the Acceptance Process

Mobile money benefits transcend enhancing financial inclusion to include building cashless and cash-light economies, curbing corruption associated with financial transactions and offers diverse perspectives to monitoring cash flow among individuals and across destinations. Ease and convenience of transacting are added advantages that come with mobile money adoption and use. This argument is premised on the behavioural decision theory (Micheni *et al*, 2013, p.10) in which cost and benefits are significant to perceived usefulness and ease of use. Thus, if the cost of mobile money is affordable and there are several benefits relative to other financial service channels, adoption and use will be high.

Building customers' trust is key to achieving critical mass. Davidson and McCarty (2015, p.4) posit that trust is a necessary precondition for trying mobile money (both as a technology and as a service), which must be high, since for most users, their first interaction with a mobile money service will be to hand over cash. Known mobile money brand, extensive above-the-line advertising, trustworthy agents, and positive word of mouth all build trust. However, the most effective way to gain a customer's trust is to ensure that customers' experience with the service is good,

most importantly at the early stages of adoption; else, customers are unlikely to become regular users. One way of winning customers' trust is by offering credible services which according to Micheni, *et al* (2013, p.11) entails protection of information or systems from unsanctioned intrusions or outflows that affect mobile money adoption (Wang *et al.*, 2003).

The licensing of MNOs as mobile money providers can increase adoption and use among millions of customers registered on mobile telecommunications network (InterMedia, 2016a, p.1). Unfortunately, Nigeria's regulatory regime explicitly excludes MNOs as main providers of mobile money services. Efforts to close this gap and retain control of financial transactions under the regulatory scope of the Central Bank of Nigeria has resulted in the introduction of agency banking (David-West, 2016, p.260). As Nigeria's financial regulation advocates for mobile money as a tool for diving financial inclusion, more favourable regulations that offer win-win business models are needed.

FUTURE RESEARCH DIRECTIONS

The study explored factors inhibiting mobile money adoption in Nigeria, with the means and approaches by which the existing financial exclu-

sion gap among the financially served, underserved and un-served, could be bridged. However, while there are several factors identified as inhibitors to mobile money adoption in Nigeria, the study did not provide the impact level of each factor, which should feed regulators, policy makers and industry players in determining how best to deploy their limited resources among several factor requirements, and obtain mobile money adoption at scale. In light of this, future studies should deploy a predictive model to determine the relative importance of mobile money inhibitors.

CONCLUSION

In closing financial exclusion gaps, the adoption and use of mobile money presents the potentials for bridging access barriers, make financial services available, affordable and ultimately facilitate use of mobile money. David-West (2016, p.271) stressed that without the successful complementary initiatives and active stakeholders participation, mobile money cannot be perceived as the magic bullet of financial inclusion. As MMOs strive to improve service quality, access and adoption, government's involvement must be pronounced in driving of financial literacy, agency banking, microfinance banking, rural enterprise development as well as mobile money awareness. The MMOs must on their part strive to improve on service reliability, quality, security and partner with the mobile network operators whose data and voice services have become a daily dosage supporting the lives of millions of Nigerians.

KEY TERMS AND DEFINITIONS

Financial Inclusion: This is a state in which all bankable members of an economy have ease of access to and use available formal financial services at an affordable cost.

Financially Excluded: These are unbanked members of an economy without access to any form of financial services.

Financially Served: This refers to banked individuals with access to a bank account either with a deposit money bank (DMB) or microfinance bank (MFB) or who make use of services provided by other financial institutions such as insurance companies or pension schemes.

Financially Under-Served: These are members of an economy who are under-banked with access to informal financial services only.

Mobile Money: The use of a mobile phone to conduct financial services using electronic accounts (e-wallet).

Mobile Money Adoption: This refers to a state in which mobile money service is accepted as either an alternative or supplement to existing financial service products.

Mobile Money Operator (MMO): This is a licensed mobile money service provider that develops and deploys financial services through mobile phones and mobile telephone networks.

Mobile Money Services: These include the range of financial services offered by MMOs, such as cash-in, cash-out, utility/bill payments, remittances (domestic and international), airtime top-up, savings, credits, etc.

E-Commerce Models, Players, and Its Future

E**Liguo Yu***Indiana University – South Bend, USA*

INTRODUCTION

Wikipedia defines e-commerce (electronic commerce) as the trading or facilitation of trading of products or services using the Internet. E-commerce is becoming a major business model in developed countries. For example, in US, the e-commerce sales as ratio of total retail sales reached 7.5% in December 2015; in China, the e-commerce sales as ratio of total retail sales reached 9.7% in July 2015; and it is estimated that globally, the e-commerce sales will reach \$ 1.5 trillion in 2018. Furthermore, e-commerce is growing and will continue to grow, especially in developing countries.

E-commerce plays an important role in our modern economy (Goldfarb, Greenstein, & Tucker, 2015), and its effect goes beyond economy and business. E-commerce is becoming an integral part of our society and our life. It is therefore necessary to clearly understand e-commerce operations and impacts. In this chapter, we examine various e-commerce models, major players, and the environmental ecosystem factors in order to understand how e-commerce has shaped our new way of conducting business and how it is going to influence our future. The remaining of this chapter is organized as follows. Section 2 reviews e-commerce history. Section 3 introduces various e-commerce models. Section 4 describes the major e-commerce players in the global business. Section 5 describes emerging models and emerging market. Section 6 describes the future trend of e-commerce. Conclusions are in Section 7.

BACKGROUND

Self-sufficiency was considered a primitive lifestyle in early human society. Once communications and interactions became popular in human society, trading gradually replaced self-sufficient economy (Watson, 2006). The advantages of commerce/trading over self-sufficient economy include the increase of productivity of human being and the increase of diversity of consuming products/services. Commerce (trading), as a basic activity of human society, can be traced back to prehistoric time and its evolution can be categorized into the following stages.

- **Barter System:** Barter system is the direct exchange of products or services with other products or services without using a medium. This kind of trading model can be traced back to 150 thousand years ago (Watson, 2006).
- **Currency System:** In currency system, standardized exchange medium, money, was introduced. With the support of currency, trading became more convenient. The development of original currency, metal coins, is believed to have originated about 500 BC.
- **Banknote:** The first development of a local banknote (paper currency) began about 700 AD in China. With its many advantages over metal coins, paper currency or paper money was gradually adopted nationally in China around 1100 AD.

- **E-Currency:** Electronic money was introduced within the modern banking system. Examples of e-currency include bank deposits, fund transfer, and electronic payment. Using e-currency, money balance and transaction history are stored in a computer system and users who have the access key could manage their money. The access key could be a bank card or an online password. The first bank card was introduced in 1946 by John Biggins, a banker in New York, and the first online banking system was introduced in 1983 by the Bank of Scotland.
- **E-Commerce:** The first e-commerce model was proposed and built in 1970s, which was long before the wide use of the Internet. It was created in student laboratories of Stanford University and Massachusetts Institute of Technology (Markoff, 2005). In the following half century, various e-commerce models are proposed, tested, and implemented (Tkacz & Kapczynski, 2009; Palmer, 1988; Kelly, 2005).

E-commerce, like any other internet-based applications, evolves with the revolution of information technology (Rayport & Jaworski, 2002). On an e-commerce platform, not only payments can be transacted electronically, placing orders, processing orders, and tracking orders all can be executed electronically. After about 150 thousand years of evolution, human beings are entering a completely different business era, which is characterized by e-commerce.

E-COMMERCE MODELS

There are many ways a business activity could be conducted online. The most commonly seen e-commerce models include B2B, B2C, and C2C, which are responsible for majority of the online business transactions. These common models together with some other models are described below.

B2B Model

In B2B (Business-to-Business) model, one business purchases products from another business and then sells the products to the final customer (Haig, 2001; King, 2015). In this model, business operations, such as product ordering, payment transactions, and order tracking, could all be accomplished online. This B2B model significantly reduces the business cost compared with the traditional business purchasing process. Table 1 lists some of the most visited B2B websites globally¹. We should not be surprised to see that most commonly visited B2B websites are in China, because China is currently the world's largest manufacturer. The retail business worldwide is importing from China. Therefore, B2B e-commerce could facilitate international trading.

B2C Model

In B2C (Business-to-Consumer) model, a business sells its products directly to the final customer (Elliott, 2002). In this model, consumers visit a B2C website and purchase products. Table 2

Table 1. Top B2B websites measured with global traffic rank

Company	Website	Global Traffic Rank	Languages	Home Country
Alibaba	alibaba.com	81	Multiple languages	China
IndiaMart	indiamart.com	1,145	English	India
Made-in-China.com	made-in-china.com	1,170	Multiple languages	China
DHgate.com	dhgate.com	1,186	Multiple languages	China

Table 2. Top B2C websites measured with global traffic rank

Company	Website	Global Traffic Rank	Languages	Home Country
Amazon	amazon.com	6	Multiple languages	USA
Alibaba	tmall.com	37	Chinese	China
JD.com	jd.com	88	Chinese	China
Walmart	Walmart.com	110	English	USA

lists some of the most visited B2C websites globally². Although Alibaba's Tmall is considered a B2C model, its operation is quite different from the others. For Amazon, JD.com, and Walmart, they are the sellers, which means they purchase products from manufacturers, store products in their own warehouses, and when orders are placed by consumers, they need to ship the products. For Alibaba's Tmall, it is just a B2C platform. Manufacturers and retailers could open a store in Tmall and Alibaba is responsible for payment transactions and the store owner is responsible for shipment. Therefore, Alibaba does not directly handle products, including purchasing, warehousing, and shipping.

C2C Model

In C2C (Consumer-to-Consumer) model, a consumer buys a product directly from another consumer (Turban, King, & Wang, 2003). Table 3 lists some of the most visited C2C websites globally. Most C2C websites, such as eBay and Taobao of Alibaba, offer services to connect consumers (sellers and buyers) of a product. In contrast, Craigslist operates on a different business model, through which it offers classified advertising services to get consumers connected.

Other Models

In addition to the three aforementioned e-commerce models, there are other Internet-based business models. Some people consider them as e-commerce and others do not. These models include C2B (Consumer-to-Business), B2G (Business-to-Government), G2B (Government-to-Business), and G2C (Government-to-Citizen). For example, in C2B model, consumers could offer their products/services online and companies can buy and pay for the products/services. Examples of C2B websites include fotolia.com, GoogleAdsense, and Amazon Affiliate Program.

Vertical e-commerce is a business model that the sellers are specialists of a kind of products and the e-commerce website is targeted to a specific group of consumers. For example, beauty.com is a cosmetics vertical e-commerce website; drugstore.com is a medicine vertical e-commerce website; zappos.com is a shoe and clothing vertical e-commerce website; and zulily.com is a vertical e-commerce website featuring clothing, toys, and home products. Although usually vertical e-commerce business is much smaller than the horizontal e-commerce business, such as Amazon, Alibaba, and eBay, which sell products of various categories, there are many vertical e-commerce websites and they play important roles in the retail industry.

Table 3. Top C2C websites measured with global traffic rank

Company	Website	Global Traffic rank	Languages	Home Country
Alibaba	taobao.com	12	Chinese	China
eBay	ebay.com	23	Multiple languages	USA
Craigslist	craigslist.org	71	Multiple languages	USA
Etsy	etsy.com	130	English	USA

4. THE BIG E-COMMERCE PLAYERS

E-commerce, like any other internet-based business, can grow fast and big without the locality limitations. Currently, the two biggest e-commerce companies worldwide are Amazon and Alibaba. Their business are described below.

Amazon

In 1995, Jeff Bezos launched Amazon.com as an online bookstore (Stone, 2013). After 20 years growth, it now becomes the most valued e-commerce company in the world. Although Amazon is mainly operated in the United States, its business has been expanded all around the world, even in the most competitive marketplace like China.

Amazon typically follows a B2C business model. It purchases products from the manufacturers, store products in its own warehouse,

and deliver the products when orders are placed by consumers. The product categories listed in Amazon include books, audio/video/games, electronics, clothing, toys, cosmetics, sports, appliance, furniture, office supplies, auto care, and more. Amazon is well known for its fast delivery and high rate of customer satisfaction.

Globally, Amazon is actively growing its business. Currently, products can be shipped to more than 75 countries that participate in the Amazon Global program. Amazon also produces consumer electronics, such as Kindle e-book reader, Fire tablet, and Fire phone. Moreover, Amazon's web service is one of the most important cloud computing providers in the world. Table 4 shows the business and finance growth of Amazon in the past 18 years.

By the end of 2015, Amazon is ranked No. 9 of the public corporations worldwide based on market capitalization. The most important fact

Table 4. Amazon's growth (data source: various websites on the Internet)

Year	Number of Employees (Thousand)	Annual Active Users (Million)	Annual Revenue (\$ Billion)	Market Capitalization (\$ Billion)
1997	0.26	1.5	0.148	2.36
1998	1.2	6.2	0.610	28.11
1999	3	14	1.640	31.04
2000	4.5	20	2.762	8.32
2001	6	25	3.122	6.82
2002	7	30	3.933	10.51
2003	8	40	5.264	24.23
2004	9	45	6.921	20.78
2005	12	50	8.490	21.55
2006	13.9	66	10.710	18.11
2007	15.8	76	14.835	37.36
2008	20	88	19.166	28.28
2009	25	105	24.509	60.30
2010	35	130	34.204	81.57
2011	55	164	48.077	93.49
2012	80	200	61.093	127.66
2013	115	237	74.452	172.47
2014	150	270	88.988	170.47
2015	220	304	107.01	282.25

about Amazon is that its business is still expanding at about 19% year to year rate of revenue growth.

Alibaba

Alibaba is an international internet giant. Fairly to say, Alibaba is not only an e-commerce company. It provides many different services to e-commerce business and consumers. Therefore, Alibaba is an e-commerce environment, in which different kinds of business operations could be executed.

Alibaba group was founded in 1999 by Jack Ma (Liu & Avery, 2009). It provides various e-commerce solutions, such platforms for B2B, B2C, and C2C. It also provides payment transaction service through its own payment system, Alipay. In addition, Alibaba contracts with many package delivery companies to provide logistics services. Big data technology is used in these services to improve the business efficiency of its partners.

That is not all. Alibaba has many other business, including travel arrangement, advertisement, news and media, music, sport, health, entertainment, financial, banking, and insurance. Alibaba also has its software products and cloud computing services. Moreover, Alibaba is actively investing in foreign countries and foreign companies, including both public and private companies. Examples are Zulily, Groupon, Snapchat, Jet.com, and Magic Leap of USA, and Paytm, Snapdeal of India.

To understand the volume of business transactions conducted on Alibaba's platforms, let's look at the sales of Singles' Day (11.11) shopping festival created by Alibaba. In November 11, 2015, a total of \$14.3 billion sales were made at Alibaba's platforms, which is more than the combinations of Black Friday sales and Cyber Monday sales in USA. Moreover, Alibaba has a 45% year to year rate of revenue growth, which is faster than its American counterpart Amazon.

As stated by the founder and executive chairman of Alibaba, Jack Ma, Alibaba is building an internet-based business ecosystem that is going to connect the world together, from cities to cities and from villages to villages. Jack ma calls his plan

EWTO (Electronic World Trading Organization). To help the readers better understand Alibaba's internet-based business ecosystem, Table 5 compares Alibaba's business with some corresponding US companies. It is worth to note that Alibaba is expanding its business both domestically and internationally. Currently Alibaba has connected buyers and sellers of more than 240 countries. Globalization is at the core of Alibaba's strategic plan over the next decade.

Other Players

Besides Amazon and Alibaba, other major e-commerce companies in the world include JD.com of China and eBay of USA. JD.com is similar to Amazon and operates with a B2C business model, and it is currently the major competitor of Alibaba in China. In contrast, eBay is an America-based C2C e-commerce website. eBay has successfully developed its business around the world, except China, where it lost its battle against Alibaba's Taobao (Ou & Davison, 2009), at least for now. Table 6 summarizes the latest financial data of Amazon, Alibaba, JD.com, and eBay. The data is retrieved in February 2016. These four e-commerce companies are responsible for about 46% of the global e-commerce GMV (Gross Merchandise Volume)³.

It is worth making the following remarks about the data in Table 6. First, Alibaba and eBay are e-commerce platforms and accordingly their revenues do not include the values of products traded on their platforms. On the contrary, the revenue of Amazon and JD.com include all the product values traded on their websites. Second, it is expected that Alibaba and JD.com could have higher growth rates in the next few years and that is why their market capitalizations is relatively higher compared to their net incomes.

Table 5. Alibaba's internet-based ecosystem (data source: various websites on the Internet)

Business Name	Service Description	Operation Method	Corresponding USA Company/Service
Alibaba.com	B2B (international)	Platform	NA
1688.com	B2B (domestic)	Platform	NA
TMall	B2C (domestic, international import)	Platform	Amazon
Aliexpress	B2C (international export)	Platform	Amazon
Taobao	C2C (domestic)	Platform	eBay
Alipay	Online payment	Directly owned	PayPal
Cainiao	Logistics	Collaborated	UPS
Alitrip	Travel arrangement	Directly owned	Priceline
Juhuasuan	Group and discount shopping	Directly owned	Groupon
AutoNavi	Map	Directly owned	Google map
Youku Tudou	Video sharing and broadcasting	Directly owned	YouTube
SCMP	Newspaper	Directly owned	Washington Post
Alimama	Online advertisement	Directly owned	Google
YunOS	Mobile operating system	Directly owned	Android
UCWeb	Mobile web browser	Directly owned	Safari
Sogou	Mobile search engine	Directly owned	Google
Aliyun	Cloud computing	Directly owned	Amazon Web Service
Baozun	E-commerce service	Partially owned	Vteams
Sina	Online news services	Partially owned	The Huffington Post
Weibo	Micro blogging	Partially owned	Twitter
Momo	Social networking	Partially owned	Facebook
Kuaidi	Online taxi dispatch	Partially owned	Uber
Meizu	Smart phone manufacture	Partially owned	Apple

Table 6. Comparisons of the financial results of the big e-commerce companies (data source: various websites on the Internet)

Business Name	Number of Employee	Monthly Active User	Annual GMV	Annual Revenue	Annual Net Income	Market Capitalization
Amazon	230,800	244 M	\$225.6 B	\$107 B	\$596 M	\$ 261 B
Alibaba	34,985	405 M	\$376 B	\$11.7 B	\$5.38 B	\$168 B
JD.com	94,615	131 M	\$71.4 B	\$28 B	-\$131 M	\$36 B
eBay	11,600	162 M	\$82 B	\$8.59 B	\$2.23 B	\$28.5 B

EMERGING MODELS AND EMERGING MARKET

Although the world e-commerce business is largely shared by Amazon, Alibaba, and several other big players, no one business and no one business

model can dominate the market forever. Some new e-commerce models have surfaced recently. The e-commerce future is unknown, especially in the emerging market.

One new e-commerce model is represented by Jet.com. It is an e-commerce website launched

in July 2015. The unique feature of Jet.com is its smart shopping cart, which can help the customer to build a shopping list with more potential savings. According to its business strategy, Jet.com makes no profit through selling products. Instead, the income is generated through member fees. Collecting membership fee is not rare in e-commerce business (Monteiro, Swatman, & Tavares, 2003). Other e-commerce companies, like Vipshop, Sephora, also have paid membership programs.

O2O (Online-to-Offline) is considered another important emerging e-commerce model (Roberts & Zahay, 2012). This model combines online shopping and offline (physical store) shopping together and provides unique shopping experiences. For example, a product could be ordered online and picked up from or delivered by a local physical store; or a service, such as movie ticket, club membership, could be ordered online and consumed offline locally. Therefore, O2O model is also called local e-commerce. It can be integrated into local business and accordingly it is well supported by the local government. O2O is becoming a more and more popular life style in China. Examples of O2O services in China include Meituan.com, 58.com. Internet giants Alibaba and Baidu also have their O2O business, which are Koubei and Nuomi, respectively. Relatively speaking, O2O business is still under development in USA. Groupon can be classified into this field.

Another important trend in e-commerce industry in the past years is that more and more customers like to shop with mobile devices. For example, in the quarter ended December 2015, Alibaba's mobile penetration rate is about 67% and this number was only 19.7% two years ago. Mobile devices, such as smart phones and tablets, provide convenient ways and pleasant experiences for users to shop online. With devices connected online all the time, the customers would like to shop more frequently. Therefore, e-commerce companies are shifting their core business from desktop computers to mobile devices.

Although e-commerce is a common business model in developed countries, especially in USA and China, it is still under development in many

other countries. There are great business potentials around the world. Using India as an example, it is estimated that its e-commerce could reach \$100 billion by 2019. Currently, Amazon, Alibaba, and India's domestic e-commerce companies, such as Snapdeal, Flipkart are fighting hard to grow their market share there.

FUTURE RESEARCH DIRECTIONS

The key factors to e-commerce, just like to any other business, are user addition and user retention. That is why JD.com is collaborating with Tencent to get more users from Wechat, a communication platform and Alibaba is building its ecosystem to maintain a sustainable customer base. Friendly user interface, secure and convenient payment method, fast and quality delivery are other important factors to improve user retention rate. For new generations of consumers, shopping is no longer the single purpose of shopping online; shopping experience could be more important than the product. Like the traditional shopping mall, entertainment, social networking, education, and more, could all be built into e-commerce. An online expectant mother club incorporating all these features to allow pregnant women to socialize, obtain parenting knowledge and experience, and most likely, share baby products shopping information, is a perfect example of social e-commerce. Another examples of social e-commerce is the online stores built on top of social networking platforms, such as Facebook and WeChat. In this model, products/service are sold to friends or followers. This is a kind of peer to peer business model and some business cost, such as advertisement, could be significantly reduced. Most importantly, with the growing usage of mobile devices that connect users all the time, social e-commerce could become more and more popular.

E-commerce companies and customers are important players in an e-commerce environment. However, they are not the only players. No business can be operated without the influence of other

factors, such as government policies, international laws, cultures, religions, and geopolitics. The roles played by different parties, such as governments and other organizations, in an e-commerce environment could be complex and their influence may shape the future business rules and models of e-commerce. A detailed study in this area is surely needed for the future research. For example, Amazon originally only collected sales tax from a few states; after a long battle between Amazon and the state governments, it now collects sales tax from 28 states. Another example is Alibaba. Currently, the stores at Alibaba's Tmall and Taobao platforms are exempted from the 4% business tax that is unavoidable for offline physical stores. No one is expected this policy will remain forever. Clearly, any future changes of this tax rule may have effect on Alibaba's business. In addition, globalization is the theme of the 21st century, to expand business in developing countries, especially those unrest regions with cross cultural and religious conflicts, is a challenging task for Amazon, Alibaba, and any ambitious e-commerce companies.

E-commerce is growing and is growing at an unprecedented speed. Its impact on our life is extraordinary. Commerce started in the prehistoric time and the business model has not changed much for thousands of years. At one time, all stores were small with merchandise sold to local consumers. But, industrial revolution finally led to the changes of our commerce model. In the 20th century, chain stores, department stores, and especially supermarkets, gradually replaced small family stores, and our lifestyle was changed. Now, less than 100 years later, information technology revolution is going to change again our commerce model, which in turn will affect our life.

7. CONCLUSION

In this chapter, we discussed e-commerce models, its big players, and its future trend. E-commerce is becoming an important integral part of our

economy and our life. E-commerce originated and developed in the era of internet and will continue to develop with the evolution of information technology. It is hard to predict the future. However, one thing we are sure is that our lifestyle will always change, including the way of doing business.

E-commerce, like any other information technology supported business activities, will play an important role in shaping our society and life. We are living in a time full of possibilities. The potential of e-commerce is yet to be realized.

KEY TERMS AND DEFINITIONS

B2B (Business-to-Business): An e-commerce activity involves two business.

B2C (Business-to-Consumer): An e-commerce activity in which a product is sold by a business and to a consumer.

C2C (Consumer-to-Consumer): An e-commerce activity in which a product is sold by one consumer to another consumer.

E-Commerce: The business activity of trading products or services online.

GMV (Gross Merchandise Volume): The total sales of the values of products by a retailer in a specific period of time.

Horizontal E-Commerce: A website that sells various categories of products.

Internet-Based Business Ecosystem: A business environment built on top of the Internet to facilitate trading between sellers and buyers and provide services for various business activities.

Local E-Commerce: An O2O model that is integrated with local business, where products/services are ordered online and consumed locally.

Market Capitalization: The total market value of a company's outstanding shares.

MAU (Monthly Active User): The average number of users that conduct business activities on an e-commerce platform in one month period.

O2O (Online-to-Offline): An e-commerce activity that combines online shopping with offline (physical store) shopping.

Social E-Commerce: An e-commerce built on top of social networking platforms, where products/services are sold to friends or followers in the social network.

Vertical E-Commerce: A website that sells a specific category of products.

INTRODUCTION

The use of electronic payment (e-payment) systems to make payments for the access to contents and services is more and more usual. Currently, for making e-payments we can use systems such as Paypal, Bitcoin, Ripple, Apple Pay, EMV. Indeed, the use of cryptocurrencies as Bitcoin has supposed a revolution in the e-payments arena (Hileman, 2014; Vigna & Casey, 2015).

This diversity of payment options with the support of different business models (pay-per-use, flat rate, the incorporation of discounts, tickets or loyalty information, etc) arises the need of systems that support different issues regarding the purchase such as the discovery of the payment information associated to the product/service with payment options supported, the negotiation of the payment option to make the payment, and the reception of a receipt of the transaction. To cope with these issues, the definition of e-payment frameworks has been proposed. These frameworks aim to facilitate, along the purchase process, the exchange of payment information and the use of different payment instruments in an easy way at the same time it guarantees interoperability, trust and security (Jaffe & Boyera, 2015; Ruiz-Martínez et al., 2012).

This article presents what an e-payment framework is, its main features and benefits, what the main e-payment frameworks proposed so far are and, the current initiatives that are being devel-

oped. For each framework developed so far, the article presents its key features and differences with previous works. The presentation of the different frameworks proposed so far will allow the reader to understand the evolution of these frameworks and how different features have been incorporated along the time. Once previous works have been presented, the article introduces the most recent work in this field, that is, the work that is being developed by W3C with its Web Payment Activity Initiative. Then, we present future research directions by indicating the main challenges to be addressed. Thus, the reader will have a broad vision of e-payment frameworks.

BACKGROUND

This section provides some information on the different phases that comprises a payment process. The knowledge of this process is fundamental to understand the different elements that are defined in an e-payment framework.

Payment Process

The process of making purchase on the Internet is divided into the following stages (Maes et al., 1999): need identification, product brokering, merchant brokering, negotiation, purchase and delivery, and product service and evaluation. Thus, once the user realizes that he/she has a need, it

gathers information regarding the product and the merchant, then, client can negotiate the conditions with the vendor. Once the conditions have been agreed, the purchase and delivery of the product is made. Finally, several processes related to user satisfaction could be performed.

Recently, the W3C's Web payments activity initiative (W3C, 2014) considered that the simplest purchase comprises four steps: publishing an asset, publishing a license, publishing an offer, and performing the purchase.

In both cases, we can point out that, in order to make a purchase, we have to manage two kinds of information: information describing the product/service and its merchant, and information regarding the payment process: payment systems available to perform the payment, receipts, etc.

ELECTRONIC PAYMENT FRAMEWORKS

This section aims to provide the definition of what an e- payment framework is, what its main features are and its benefits.

Definition

In the literature there are different definitions of what a e-payment framework is. Next, the most relevant are presented.

Fischer et al. (2002) consider that an electronic payment framework aims to integrate payment instruments into e-commerce applications and should, at least, address the specificity of the payment instrument and the underlying protocol.

In SEMPER Framework for Secure Electronic Commerce (Schunter, 1999; Lacoste et al., 2000), it is considered that, from a technical point of view, a payment framework describes a generic model for performing e-commerce transactions between two parties through a set of services (supporting, transfer, exchange, commerce services) enable the integration of any payment protocol and product in such as way that applications were not restricted

to the use of specific protocols or proprietary solutions or technology.

Ruiz-Martínez (2015) mentions that the purpose of a web payment framework is to facilitate the purchase process and the exchange of payment information, supporting that different payment instruments can be used and guaranteeing interoperability, security, and trust.

In this paper a payment framework is defined as a set of extensible elements and/or services, generally, organized within a set of layers and that is designed to facilitate the use of different payment systems in a unified manner during a payment process. Thus, for the developers of payment-based applications, the incorporation of new payment systems is easier, transparent and can enhance user's trust (Gefen et al., 2003; Wareham et al., 2005).

Main Features

The different features that an e-payment framework should offer are:

- *The support of different payment instruments and their underlying protocols.* It should support different kinds of payment models such as credit or debit, using different payment instrument such as credit cards, e-checks or digital cash, and different payment protocols (Bitcoin, EMV, etc). This support should be made through a generic Application Programming Interface (API).
- *The support of different kinds of devices for making the payment and storing payment information.* The payment could be made through desktop computers, smartphones, ebooks readers or automobiles. It should also support the use of different devices that could increase security, such as secure elements or secure storages.
- *The specification and exchange of the payment information associated to the purchase.* Payment information (prices, pay-

ment systems supported, etc) should be described in some format that allows its automatic processing and exchange.

- *The negotiation of the payment systems, prices and conditions of the purchase.* Customer and merchant might support different payment systems and be interested in different conditions that should be negotiated at the beginning of the payment process.
- *Digital receipts and loyalty information.* During a purchase process it is also important that vendor provides a receipt of the transaction. Additionally, some loyalty information could be sent. This information could also be used later to obtain better conditions in the next purchases such as better prices, additional services, etc.
- *Extensibility.* The framework should support the inclusion of new payment systems in a seamless, transparent and uniform way.
- *Security.* It should provide secure mechanisms to guarantee the exchange of payment information and identify the different participants in the system. It is specially relevant to guarantee non-repudiation and the secure identification of the parties.
- *Privacy.* Purchase sensitive information should be protected.

The design of an e-payment framework should be made taking the following principles into account (Sporny, 2014): broad individual empowerment, maximize competition, respectful of the law, broadly implementable and data portability.

Benefits

The main benefit of introducing a payment framework is that the development of applications and solutions based on payment will reduce its development costs and increase confidence in its security (Lacoste, 2000) (Ruiz-Martínez et al., 2012) (Ruiz-Martínez, 2015). This kind of framework can increase interoperability between the

different stakeholders and the different payment methods (Web Payments Interest Group Charter, 2016), which will suppose a broader use of payments, more competition in the payment area and will prevent that a payment vendor establishes a monopoly (Web Payments Interest Group Charter, 2016). Furthermore, it can also enhance user experience and trust (Hope-Bailie et al., 2015; Gefen et al., 2003) and facilitate that customer and merchant can use their preferred payment instrument and schemes (Ruiz-Martínez, 2015; Hope-Bailie et al., 2015).

PAYMENT FRAMEWORKS PROPOSED

This section presents the main frameworks that have been proposed so far. We present them in a chronological way to understand how they have evolved and the different features that they have been incorporated over time.

The main frameworks proposed so far are: Joint Electronic Payment Initiative (JEPI), Secure Electronic Marketplace for Europe (SEMPER), W3C Common Markup for micropayment per-fee-links, Internet Open Trading Protocol (IOTP), Meng and Zhang's proposal and Ruiz-Martínez et al.'s proposal (PayFrameworks) (Ruiz-Martínez et al., 2012). Next, we describe briefly each framework.

Joint Electronic Payment Initiative (JEPI)

JEPI was a joint proposal between W3C and CommerceNet consortium. Its aim was to automate the selection of the payment protocol most suitable for client and merchant for any given transaction. For this purpose, JEPI defined two protocols as extensions of HTTP (see Figure 1): Protocol Extension Protocol (PEP) and Universal Payment Preamble (UPP).

PEP is a generic negotiation protocol that allows that a user agent and a Web server can know the extension modules they support each

other and negotiate the different parameters that will be used in these modules. In JEPI, PEP is the cornerstone for UPP.

UPP (UPP,1997) is the core of JEPI and consists of a specific extension module for negotiating payment information used in a transaction: payment instrument, brands, and payment protocol. Each payment system is considered a PEP extension module and it is identified by means an URL. Furthermore, JEPI also defines a mechanism for initiating the payment system chosen.

This framework did not address different issues such as security, the negotiation payment systems (it was oriented to the negotiation of payment instruments), different payment models and operation modes and, finally, the definition of payment information for being embedded in the Web or APIs for wallets.

Secure Electronic Marketplace for Europe (SEMPER)

SEMPER was a project partially funded by the European Union and it was formed by a consortium around 20 companies, financial institutions, European universities and technological/research institutes. Its purpose was to work in different issues related to e-commerce in insecure networks such as legal, technical and social issues. They aimed to define an open architecture that was

independent of the network architecture, operating system and software used. This architecture supports its evolution through the inclusion of new components by means of plug-ins. Its architecture is divided in four layers: business, exchange, transfer and supporting services.

Within its objectives, one of the most important ones was the design and development of a generic payment service (see Figure 2) that provides a framework that allows business applications the support of payment in a transparent way without being to know the different particularities of the different payment methods. The main component of this service is a hierarchy of APIs for the transfer of value. This hierarchical API reflects the separation according different payment models. Thus, this hierarchy consists of a common API for all payment methods and specific extensions for each model. The different models in which this API is divided are digital money and account-based systems (see Figure 2).

In addition to these interfaces, this generic service supports other features such as mechanisms for selecting the payment instrument for the transaction, information services, control and management (that makes possible to support the development of business applications that use the generic service), tools and the needed framework for incorporating any payment system in the

Figure 1. JEPI framework

generic payment service. Each specific payment system implements some of these APIs.

The main strength of this proposal is the definition of its wallet from the generalization of the different kind of payment systems. This framework is more oriented to the development of desktop applications than Web applications. Then, it does not define how payment information can be incorporated to the Web and it does either define how to encapsulate payment messages and how the wallet exchange them with the server wallet.

W3C Common Markup for Micropayment Per-Fee-Links

The W3C Micropayment Working Group proposed the Common Markup for micropayment per-fee-links (CMMPFL). The goal of this specification was to define an extensible mechanism that allowed embedding, in a Web page, all the needed information to initialize a micropayment system (amounts and currencies, payment systems, etc) when a payment is required to access a Web content. Thus, it aimed at different micropayment wallets could co-exist in an interoperable way.

This specification, to the best of our knowledge, is the first specification in introducing the concept of payment link or per-fee-link. The goal of these links is to make easy the purchase process of an

electronic product (Web page, image, etc) as much as possible: as simple as clicking on a Web link.

Thus, this specification was centered on how merchant sent, in the HTML web page, payment information to the client through the Web browser. This information could be included in the Web page by means of Java Applets or ActiveX components or by means of RDF. For the management of this information, it was proposed the use of a module called per fee link handler, which invokes to the different wallets that implement the specific payment protocols. However, this project did not define a Web API for invoking the wallet to perform payment process.

Internet Open Trading Protocol (IOTP)

IOTP was submitted to the Internet Engineering Task Force (IETF) (Burdett, 2000) with the objective of becoming it in a standard and interoperable protocol to make business on the Internet. Namely, its main goal was to provide a payment system independent protocol to make B2C transactions and that encapsulates any payment protocol.

The main IOTP feature to point out is that the payment process was designed so that it was independent of the payment system and defined how the messages of the e-payment system are encapsulated in IOTP. Associated to the protocol,

Figure 2. SEMPER payment framework

an API that considers different types of transaction (purchase, refund, value exchange, authentication, withdrawal, deposit, inquiry and ping) was defined.

In the IOTP v1.0 some issues to be improved were detected and were specified as a set of requirements for the version 2.0 of the protocol. The issues found were: the offer request is not specified in the protocol, it does not support the negotiation of prices, it does not use the XML Digital Signature (XMLDsig) scheme for the support of e-signature in IOTP. However, IOTP 2.0 version was not developed.

PayFrameworks

Payment frameworks for the purchase of electronic products and services (PayFrameworks) (Ruiz-Martínez et al., 2012) defines a new comprehensive framework (see Figure 3) that aims support the purchase of the main kind of electronic products and services (e-products hereafter). Namely, it considers Web products, Web services, Session Initiation Protocol (SIP) sessions and streaming sessions based on the use of the Real Time Streaming Protocol (RTSP).

For the purchase of e-products accessed by means of HTTP, the per-fee-link framework and the web services framework have been defined (see Figure 3). Both use the Extended Payment Protocol (EPP) (Ruiz et al., 2009), an oriented-session payment protocol, for the exchange of payment information and payment protocol messages. Furthermore, it defines extensions to HTML, WSDL, WS-Policy and UDDI to include payment information.

For SIP and RTSP a set of extensions to these protocols has been proposed (Ruiz-Martínez et al., 2008; Ruiz-Martínez et al., 2016). These extensions are used to incorporate payment information to these protocols.

Independently of the kind of protocol used, all extensions made to specify payment information are based on the use of the same ontology and the same set of XML schemas (Payment Information Schemas and Ontologies layer in Figure 3). Furthermore, to facilitate that the implementation of an e-payment system can be used in the different frameworks, all the frameworks use a generic API that have been defined to support any e-payment system (see in Figure 3 how the different protocols connect with the Generic Wallet API layer).

Figure 3. PayFrameworks

DISCUSSION

After analyzing the main frameworks proposed, we can find the evolution they have experimented. The first framework (JEPI) was only centered on exchanging payment information through HTTP. Then, other elements have been considered such as embedding payment information in the Web (CMMPFL or PayFrameworks) by means of its description in some language that allows its automatic processing (CMMPFL, IOTP, PayFrameworks), even some semantic information has been defined to be able to perform reasoning (PayFrameworks). In these frameworks is fundamental also the definition of generic APIs that allow the support of different payment systems, protocols and instruments (SEMPER, IOTP, PayFrameworks).

However, these frameworks have not been standardized and are not being currently used. The main reasons we can found is that, when these frameworks were defined, the use of e-payment systems on the Internet was not extended, some technologies were not mature enough or its use is not extended (semantics, security) and that in the definition of these frameworks all stakeholders did not participate, which make difficult that these frameworks were broadly extended (Jaffe & Boyera, 2015; Ruiz-Martínez, 2015).

CURRENT E-PAYMENT FRAMEWORK INITIATIVES

Nowadays, the use of e-payments is quite extended and mobile payments are growing and are becoming an important mean to make payments on the Internet. Indeed, Garnet predicts by 2017, that in the US, 50% of US Digital Commerce Revenue will be driven by the customer's engagement behaviour (Garnet, Inc, 2015). However, in e-payments there are several challenges that have arisen such as an important shopping cart abandonment, high level fraud in credit card payments, and an important number of payment solutions available but that

cannot be offered on all merchants' sites or on all devices (W3C, 2014). In order to cope with these problems and make easy payments on the Web, the W3C launches the Web payments Activity. In the next section we present the work W3C Web Payment Activity is making through Web Payments Interest Group, Web Payments Working Group and Web Payments Community Group.

W3C's Web Payment Activity

The W3C has launched the Web Payments Activity with the aim of making payments easy and more secure on the Web, improve interoperability and foster competition and innovation in web payments. Namely, the goals this activity pursues are (W3C, 2015):

1. Support the choice of user's preferred payment solution independently of the device used.
2. Make easy merchants can support a number of payment solutions in a transparent way.
3. Easier application monetization for developers.
4. Less entry barriers for new payment solution providers.
5. Decreasing online fraud.
6. Supporting in an effective way micropayments and paywalls.

This activity is being developed by the Web Payments Interest Group, Web Payments Working Group and Web Payments Community Group. It started at the end of 2014 and it is expected to be finished by the end of 2017. Its roadmap can be found in (Sporny et al., 2015).

Conceptually, the first version of the payment framework proposed in this specification contains the layers that are shown in Figure 4: transport layer, payment instruments negotiation layer and payment instrument layers. There are also other supporting modules/layers for the layers we have just mentioned such as Data/User privacy, protocols and flows information, and data format and API.

The goal of the *transport layer* is to ensure convergence among payment solutions covering the possibility of making transactions online through HTTP or offline through protocols based on proximity as NFC, BTLE, etc.

The *payment instruments negotiation layer* will support that client and merchant can agree the payment instruments to be used.

The *payment instrument layer* is responsible for working with a specific payment instrument layer. They have considered different kind of payment instruments: token-based payments, push-based payments, credit card-based payments, cryptocurrencies and coupons/loyalty. This layer should also support new kinds of payment instruments that could appear in the future. This layer, apart from managing payment instruments, needs to manage other issues related to the payment process such as the management of credential, the authentication between parties, the access to secure hardware where different information could store and manage in a more secure way (information of the payment instrument, credentials or information to perform authentication such as keys and certificates), and the generation of receipts associated to the transaction.

Additionally, to these layers, the frameworks defined two layers that are used as building blocks: *data/user privacy module* that is in charge of managing the information exchanged between the parties in order to preserve user privacy and,

the *protocols & flows, information, data format & API* module that is responsible for managing the protocols and the flow of information, the information that needs to be exchange between the parties and the API for its use.

In these layers we can point out the presence of wireless transport protocols (for mobile payment systems), the use of secure hardware to improve payment security and the management and preservation of user personal information.

This initiative considers all the elements introduced in previous works regarding payment frameworks. Furthermore, some technologies and its use such as security and semantic information technologies are more mature. Therefore, the authors consider that if the work made in this initiative is supported by the different stakeholders in a few year, this framework could be standardized and the use and interoperability of (mobile) e-payment systems could be a success.

FUTURE RESEARCH DIRECTIONS

Many of the future research directions coincide with W3C's work and objectives since it aims to address the different issues that a comprehensive Web payment framework should satisfy and in its definition main stakeholders are involved. Next, we present the different future research directions.

Figure 4. W3C draft payment framework

First, a Payment API that supports different kind of payment methods and that payments can be made using different types of devices should be defined. Thus, it is necessary to research to provide an API that can be used both desktop computers and mobile devices in a similar way through different websites, which is fundamental for reducing card abandonment. The case of payment in mobile devices is specially challenging due to the limitations of these devices compared to a desktop computer. It is also important that the specification is agreed by main stakeholders so that, finally, is developed and used in web browsers.

Second, related to the previous issue, it is required to investigate which is the best approach (plug-in, extensions, independent application, etc) to incorporate payment software that implements the mentioned API into web browsers to support different payment protocols and instruments. This process should be made in a simple way and that allows the user establish payment preferences in an easy way. Therefore, it is also necessary to investigate in the different issues regarding usability and trust in the use of this software.

As third future research direction we should consider the incorporation of secure hardware devices to increase payment security. This issue is especially important in mobile devices since it requires the definition of a layer/middleware that is independent of the operating system.

Four, we should investigate in how in the definition of new vocabularies W3C is defining it is possible reuse existing terms and relationships that are already defined in some quite extended vocabularies such as GoodRelations (Ashraf et al., 2011). In the event these the terms cannot be reused and combined into a single vocabulary, we should investigate in how to make a mapping between terms of the different vocabularies.

As final future research direction we have identified to guarantee security and privacy in the different exchanges. Thus, we should investigate how the framework, on the one hand, is able to protect that exchanged information cannot be modified or observed, and on the other hand,

is able to provide enough evidences to perform correctly non-repudiation processes. During transactions is also fundamental the definition of mechanisms so that the different parties can be identified and that we can establish some level of trust that can be used to decide whether we make a payment with an entity that we have not made purchases previously.

CONCLUSION

Currently, there are different (mobile) e-payment systems to perform a purchase on the Internet. In this situation where multiple options are available, e-payment frameworks arise in order to facilitate the discovery of payment information, payment systems and the negotiation and selection of the payment system to perform a purchase.

This paper has characterized payment frameworks and introduced the main electronic payment frameworks that have been defined so far as well as the most recent activity conducted by the W3C through its Web payment initiative. This analysis shows that electronic payment frameworks have gained in complexity and now more elements are needed in order to facilitate the discovery of payment information and perform the payment process. However, technology now is more mature than before and all the stakeholders are interested in the support of e-payments. Therefore, now we are in the conditions so that the development of the payment framework is a success. This will require overcoming some challenges regarding the definition of generic APIs, the registration and use of wallets, and interoperability, security, trust and privacy issues.

KEY TERMS AND DEFINITIONS

Electronic Payment Framework: A set of extensible elements and/or services, generally,

organized within a set of layers and that is designed to facilitate the use of different payment systems in a unified manner during a payment process.

Electronic Payment Protocol: A protocol to make electronic payments.

Electronic Payment System: A system that establishes how to pay for goods or services electronically during the execution of a financial transaction.

Micropayment: A payment where the amount to be paid is very small.

Paywall: A system that only gives access to web contents to those users that have a paid subscription.

User Payment Agent: It is being used as a synonym of wallet.

Wallet: A software or service that supports one or more payment systems.

Factors Determining E-Shopping Compliance by Nigerians

E**Adamkolo Mohammed Mohammed Ibrahim***University of Maiduguri, Nigeria***Md. Salleh Hj. Hassan***Universiti Putra Malaysia, Malaysia***Sarina Yusuf***Universiti Putra Malaysia, Malaysia*

INTRODUCTION

Online shopping (e-shopping) is increasingly gaining acceptance in many societies despite the myriad of circumstances and factors that influence its acceptance (Venkatesh, Thong & Xu, 2012). These factors often border around consumers' cognitive perceptions toward service quality and technology adoption expectancies (Chen & Macredie, 2010). The literature on e-commerce in Nigeria focuses on the advantages and constraints of online shopping, with little attention to the factors that influence e-shopping compliance. This chapter believes that a clear understanding of the effects of the factors would provide e-tailers with the opportunity to formulate tailored strategies to making e-shopping accepted by consumers.

The primary concept of this study is adoption of e-shopping. E-shopping refers to the act of purchasing products or services over the Internet (Business Directory, 2016; Lims & Dubinsky, 2004). Liao and Cheung (2000) described e-shopping as "virtual shopping over the Internet" (p. 3). According to Alam and Noor (2009), the adoption of technology, innovation or information and communication technology (ICT) is the means to enable businesses to compete on a global scale, with improved efficiency, and closer customer and supplier relationships. Therefore, acceptance of e-shopping by Nigerians is regarded as a crucial

condition for consumers and e-tailers to overcome challenges associated with conventional shopping (Tarute & Gatautis, 2014).

This study was performed based on the extended version of the unified theory of acceptance and use of technology (UTAUT2) model perspective. A new conceptual model was designed, incorporating constructs from the service quality (SERVQUAL) model (see Parasuraman, Zeithaml & Berry, 2002). AlAwadhi & Morris, (2008) and Venkatesh, Morris & Ackerman (2000) support such modifications. The urge to understand the factors affecting online shopping from both cognitive (UTAUT2) and SERVQUAL perspectives prompted this hybridization. This chapter was structured into literature review, methodology, results and discussion and conclusion sections.

BACKGROUND

Online Shopping in Nigeria

Online shopping is gradually becoming trendy, especially among the elites, middle-income earners, students and technocrats in Nigeria (Aminu, 2013). About a decade earlier, however, online shopping was much less heard about (Chang & Samuel, 2004) much less of adoption. Most e-tailers in the country offer a wide range of as-

sorted products and services online. However, most Nigerian consumers are slow at complying (accepting) online shopping (FOTN, 2015).

The literature suggests that the low level of online shopping acceptance among Nigerians might have links with cognitive, service quality and other social and economic factors (Amina, 2013; FOTN, 2015). These factors are believed to affect the consumers' behavior to purchase products online (Chukwu & Uzoma, 2014). Some of popular e-tailers include Konga, Jumia, Glamor and Manna Stores (Aminu, 2013).

LITERATURE REVIEW

The Concept of Consumer Acceptance of Technology

This study adopted the extended version of the unified theory of acceptance and use of technology (UTAUT) model developed by Venkatesh, Morris, Davis & Davis (2003). Venkatesh, Thong & Xu (2012), formulated the extended UTAUT (i.e., UTAUT2) model. The model focuses on consumer adoption of technology. It was developed based on a comprehensive synthesis of past information and communication technology (ICT) acceptance research. The UTAUT model has four key variables namely, performance expectancy (PE), effort expectancy (EE), social influence SI, and facilitating conditions (FC). Those constructs are theorised to influence behavioral intention to use ICT or ICT use. Those four constructs are retained in the UTAUT2 model's consumer technology acceptance and use context.

The literature defines performance expectancy as the degree to which using a particular technology provides benefits to consumers in performing certain activities (online). Effort expectancy is defined as the degree of ease linked with consumers' use of technology. Social influence is defined as the degree to which consumers perceive that important others or people that matter to them (e.g., family, friends and colleagues) believe that they

should use a particular technology. The literature defines facilitating conditions as the consumers' perceptions of the resources and support available to guarantee smooth use of a technology (AlAwadhi & Morris, 2008).

Performance expectancy, effort expectancy and social influence are theorised to influence use behavior. In the original UTAUT2 model, individual difference variables namely, age, gender and experience are theorised to moderate various relationships. However, the moderation apparatus has been jettisoned in this chapter because this study is preliminary. Venkatesh, et al. (2012) incorporated three additional constructs, namely hedonic motivation (HM), price value (PV) and habit (HT).

Prior studies have discovered that many consumers use a technology chiefly for the fun and joy they derive from it (Brown & Venkatesh, 2005; van der Heijden, 2004). Hence, the researchers incorporated hedonic motivation construct into the model. Hedonic motivation has been found to influence ICT use in online purchase context (Chan, Gong, Xu & Thong, 2008). The researchers define hedonic motivation "as the fun or pleasure derived from using a technology" (p. 161). Brown and Venkatesh (2005) and Thong, et al (2006) explained that construct plays an important role in determining technology acceptance and use.

Previous studies have established that consumers usually bear the monetary cost of online transaction (Thong, et al., 2006) rather than employees. Chan, et al. (2008) suggests that the cost and pricing structure influence consumers' technology use. For instance, there is evidence that the popularity of instant messaging (IM) services of WhatsApp social media application in Nigeria is due to the low (virtually free) cost relative to other types of mobile Internet applications such as short messaging services (SMS) (FOTN, 215). In UTAUT2, price value is conceptualized together with the quality of products or services to determine the perceived value of products or services (Zeithaml, 1988; Venkatesh, et al., 2012). Cited in Venkatesh, et al. (2012), Dodds, et al.

(1999) defines price value as “consumers’ cognitive trade-off between the perceived benefits of the applications and the monetary cost for using them” (161). Venkatesh, et al. (2012) posits that the price value of using a technology is positive when the benefits are perceived to be greater than the monetary cost.

Habit has been introduced into the model because prior research found that some consumers tend to use a technology with automaticity (e.g., Kim & Malhotra, 2005; Venkatesh, et al., 2012). Habit is defined as the extent to which consumers tend to use a technology to perform a behavior (shopping) automatically because of learning (prior experience) (Limayem, et al., 2007). Kim and Malhotra (2005) and Limayem, et al. (2007) found that habit influences technology use.

Findings from a cross-cultural study of ICT adoption performed by Oshlyansky, Cairns and Thimbleby (2007) reveal that performance expectancy, effort expectancy and social influence predict use intention. Šumak, Polančič and Heričko (2010) found social influence has a significant impact on students’ behavioral intention to use moodle; and, behavioral intention is a powerful predictor of the use of ICT (Baptista & Oliveira, 2015). In a research conducted by Cheng, Liu, Song and Qian (2008), the validity of the UTAUT model was investigated using 313 intended users of Internet banking in China. The result identified performance expectancy and social influence as strong predictors of behavioral intention (Taiwo & Downe, 2013).

The researcher performed some critical adjustments as is normally accepted in literature (e.g., AlAwadhi & Morris 2008) in the model by incorporating three constructs, namely reliability (RL), empathy (EM) and responsiveness (RS) from the service quality (SERVQUAL) model (see Parasuraman, et al., 2002). This chapter deems those adjustments as necessary because the literature suggests that service quality factors significantly determine online shopping acceptance (e.g., Venkatesh, et al., 2000).

The Concept of Service Quality

As a marketing strategy, service quality (SERVQUAL) is a concept that has aroused considerable interest in the research literature because of the difficulties in defining and measuring it (Parasuraman, et al., 2002). Service quality has been defined severally. A commonly used definition is the one that defines service quality as the extent to which a service meets customers’ needs or expectations (Lewis & Mitchell, 1990). Service quality is also the difference between customer expectations of service and perceived service (van Iwaarden, van der Wiele, Ball & Millen, 2003). The literature underscores that if expectations are greater than performance, then perceived quality is less than satisfactory; hence, customer dissatisfaction occurs (Parasuraman, et al., 2002). Measuring service quality allows for comparison between pre- and post-service changes, for the location of quality-related problems and for the establishment of clear standards for service delivery (Lewis & Mitchell, 1990).

The SERVQUAL instrument has been adjudged the predominant method used to measure consumers’ perceptions of service quality. The modified version of the model, which was adopted by this study, has five generic dimensions or factors: tangibles, reliability, responsiveness, assurance and empathy (van Iwaarden, et al., 2003). The reviewed model has five key constructs (van Iwaarden, et al., 2003; Parasuraman, et al., 2002) as follows:

1. **Tangibles:** Physical facilities, equipment and appearance of personnel;
2. **Reliability:** Ability to perform the promised service dependably and accurately;
3. **Responsiveness:** Willingness to help customers and provide prompt service;
4. **Assurance:** Knowledge and courtesy of employees and their ability to inspire trust and confidence, competence, courtesy, credibility and security; and

5. **Empathy:** Caring, individualised attention that the organization provides to its customers, as well as access, communication, and understanding the customer.

Hypotheses of This Study

- H₁:** There was significant relationship between performance expectancy and e-shopping acceptance
- H₂:** There was significant relationship between effort expectancy and e-shopping acceptance
- H₃:** There was significant relationship between social influence and e-shopping acceptance
- H₄:** There was significant relationship between facilitating conditions and e-shopping acceptance
- H₅:** There was significant relationship between hedonic motivation and e-shopping acceptance
- H₆:** There was significant relationship between price value and e-shopping acceptance
- H₇:** There was significant relationship between habit and e-shopping acceptance
- H₈:** There was significant relationship between reliability expectancy and e-shopping acceptance
- H₉:** There was significant relationship between empathy and e-shopping acceptance
- H₁₀:** There was significant relationship between responsiveness expectancy and e-shopping acceptance

METHODOLOGY

The research instrument consisted of a 40-item questionnaire that was pre-tested and administered face-to-face to a sample of 380 students selected from a population of 2,750 undergraduate students on campus at Yobe State University Damaturu. Since e-shopping is a novel online activity in the society, it was presumed that not all students might have experienced shopping online. Therefore, purposive sampling method was adopted. Moreover, only students that had been confirmed to have had experienced online shopping at least once were selected for participation in the study.

Data collection lasted for two weeks, and with 337 questionnaires retrieved, an 88.7% return rate was achieved. However, data of only 300 valid cases were analysed since 37 cases were eliminated during data sorting and cleansing due to incomplete responses and response inconsistency. The descriptive analysis was performed using the statistical package for social sciences (SPSS) software version 22.0 and five-point Likert Scale was used to gauge respondents' perceptions. Moreover, a committee of expert scholars validated the questionnaire. The degree of reliability of the items in the scale ranged from $\alpha = .755$ to $\alpha = .876$.

Furthermore, this study was performed based on the UTAUT2 model perspective. The model was modified by incorporating three additional predictors, namely reliability expectancy, empathy and responsiveness expectancy from the SERVQUAL model (see Figure 1).

Table 1. Performance expectancy as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	Doing e-shopping increases my chances of achieving things that are important to me in the online purchasing process.	2.53	.836
2	I can save time in the online purchasing process when I do e-shopping.	2.43	1.04
3	I find doing e-shopping very useful in the online purchasing process.	2.32	.858
Overall Mean		2.43	.911

Figure 1. The conceptual model of this study, illustrating the 10 independent variables and the dependent variable
(adopted with adjustments from Venkatesh, et al. (2012))

RESULTS

Performance Expectancy

The moderate mean value ($M = 2.53$, $SD = .836$) of the first item in the scale indicates many of the respondents believed that conducting e-shopping would increase their chances of achieving that were important to them in the online purchasing process. Other items were less important (see Table 1).

Effort Expectancy

The item that gauged the respondents' belief that learning how to do online shopping was easy for them scored the highest mean value in the scale, even though the intrinsic value of the mean score

was moderate ($M = 2.55$, $SD = 1.06$). Other items were moderately important (see Table 2).

Social Influence

The finding indicates the level of the respondents' perception that people who were important to them could affect their acceptance of online shopping is low. Other items were less important (see Table 3).

Facilitating Conditions

The respondents' perception that access to technical help that could guarantee smooth performance of online shopping affected their acceptance of e-shopping is moderate. All other items were moderately important (see Table 4).

Table 2. Effort expectancy as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	Learning how to do e-shopping is easy for me.	2.55	1.06
2	It is easy for me to become skilful at doing e-shopping.	2.51	.975
3	I find doing e-shopping easy to use.	2.50	.982
	<i>Overall Mean</i>	<i>2.52</i>	<i>1.01</i>

Table 3. Social influence as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	People whose opinions I value prefer that I do e-shopping.	1.95	.831
2	People who influence my behavior think that I should do e-shopping.	1.91	.793
3	People who are important to me think that I should do e-shopping.	1.83	.733
	<i>Overall Mean</i>	<i>1.90</i>	<i>.786</i>

Table 4. Facilitating conditions as factors affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	I have the knowledge necessary to do e-shopping.	2.77	1.12
2	I feel comfortable doing e-shopping.	2.72	1.05
3	I have the resources necessary to do e-shopping.	2.24	.836
	<i>Overall Mean</i>	<i>2.58</i>	<i>1.00</i>

Hedonic Motivation

The respondents' perception whether they believed that doing e-shopping was enjoyable was high, even though the actual value of the mean score was moderate ($M = 2.60$, $SD = 1.12$). Concisely, many of the respondents believed that they felt entertained when they do e-shopping (see Table 5).

Price Value

Many of the respondents liked searching for cheap products online. This item scored the highest mean value in the scale. However, the actual mean value of the item is moderate ($M = 2.62$, $SD = 1.06$). In short, not so many of the respondents believed that

the price value of online products of the e-shops was appealing (see Table 6).

Habit

The finding shows most of the respondents did not believe that doing e-shopping had become their habit as indicated by the very low or just low mean values (see Table 7).

Reliability Expectancy

Many of the respondents believed that purchasing products online was reliable as indicated by the moderate mean values. However, not so many of the respondents believed that online stores keep to time ($M = 2.41$, $SD = .733$) (see Table 8).

Table 5. Hedonic motivation as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	Doing e-shopping is enjoyable.	2.60	1.12
2	Doing e-shopping is very entertaining.	2.56	1.11
3	Doing e-shopping is fun.	2.36	1.00
Overall Mean		2.51	1.08

Table 6. Price value as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	I like to search for cheap product deals online.	2.62	.106
2	I can save money by examining the prices of products for e-shopping online.	2.08	.912
3	Online shopping offers better value for my money.	2.07	.799
Overall Mean		2.26	.601

Table 7. Habit as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	Doing e-shopping has become a habit for me.	1.90	.787
2	I am addicted to doing e-shopping.	1.58	.496
3	I must do e-shopping.	1.48	.501
Overall Mean		1.65	.595

Table 8. Reliability expectancy as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	You get what you ordered from online stores.	2.90	1.07
2	Online stores are dependable because the price shown on the website is the actual amount billed.	2.69	1.11
3	When online stores promise to do something by a certain time, they do so.	2.41	.733
Overall Mean		2.67	.971

Empathy

Many of the respondents regarded the service quality of the e-tailers as empathetic as indicated by the moderate the mean values. However, not so

many of the respondents believed that the service quality of the e-tailers was any empathetic ($M = 2.37$, $SD = .995$) (see Table 9).

Table 9. Empathy as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	Employees of online stores are polite to customers.	2.94	1.01
2	Employees of online stores provide customers individual attention.	2.72	.971
3	When customers have problems, employees of online stores are sympathetic and reassuring to customers.	2.37	.995
Overall Mean		2.68	.992

Responsiveness Expectancy

Many of the respondents believed that the online stores were responsive to consumers' needs. This is indicated by the moderate mean values. However, not many of the respondents believed that the online stores were any responsive to customers' needs ($M = 2.16$, $SD = .842$) (see Table 10).

DISCUSSION

Not quite many of the respondents ($M = 2.43$, $SD = .911$) believed that doing shopping online would yield remarkable outcomes (performance expectancy) to them (refer to Table 1). However, quite a number of them ($M = 2.52$, $SD = 1.01$) believed that doing shopping online would be effort-free, and easy (refer to Table 2). Similarly, not quite many ($M = 1.90$, $SD = .786$) of the respondents believed that important others would influence their e-shopping compliance (refer to Table 3). This suggests that social relationship is not important in influencing their e-shopping compliance.

Contrary to the result of social influence construct, quite many ($M = 2.58$, $SD = 1.00$) of the respondents believed that access to technical help would influence their e-shopping compliance (refer to Table 4). This suggests that consumers prefer to shop online when they are sure of the availability of someone that would help them in case they were stuck while shopping online. Similarly, quite many ($M = 2.51$, $SD = 1.08$) of the respondents believed that they enjoyed shopping online (refer to Table 5). This suggests that consumers are interested to shop online.

Contrary to the result of hedonic motivation construct, not quite many ($M = 2.26$, $SD = .601$) of the respondents believed that the price value of products promoted online did not influence their e-shopping compliance (refer to Table 6). This suggests that consumers are not impressed by the prices of products tagged on the websites of e-stores. Similarly, not many of the respondents believed that they did e-shopping because it had become their habit (refer to Table 7). This suggests that consumers prefer to do e-shopping not necessarily because they are addicted to it.

Table 10. Responsiveness expectancy as factor affecting acceptance of e-shopping

Measurement Scale			
S/No	Item	Mean	SD
1	Employees of online stores understand customers' needs.	2.94	1.01
2	Employees of online stores respond to customer requests promptly.	2.72	.971
3	Employees of online stores have customers' best interests at heart.	2.16	.842
Overall Mean		2.61	.941

Quite many ($M = 2.67$, $SD = .971$) of the respondents believed that the services of the online stores were reliable (refer to Table 8). This suggests that consumers believe that the service delivery quality of the online stores is reliable and dependable. Similarly, quite many ($M = 2.68$, $SD = .992$) of the respondents believed that the online stores were empathetic to customers' needs (refer to Table 9). This indicates that customers believe that online stores treat customers' needs with utmost care.

Similarly, quite many ($M = 2.61$, $SD = .941$) of the respondents believed that the online stores were responsive to customers' needs by keeping their words and being prompt (refer to Table 10). This suggests that customers believe that online keep promise. However, not so many ($M = 2.28$, $SD = .825$) of the respondents believed that doing e-shopping was any favorable to them. This suggests that not so many people do online shopping. This may be associated with the relatively low level of broadband penetration in Nigeria, relatively low level of access to online applications and particularly, the novelty of online shopping in the country (Emmanuel, 2015; FOTN, 2015).

FUTURE RESEARCH DIRECTIONS

This chapter recommends that future research should focus on investigating e-shopping compliance by consumer group categories, rather than general consumers. For example, there is need to understand the e-shopping readiness (acceptance) by public (civil) servants, employees of private (corporate) organizations, urban mothers, politicians, academicians, etc. Conducting exploratory studies to understand the online shopping characteristics of multiple groups of Nigerian consumers could be of immense benefits to both e-tailers and researchers as follows, given that the online shopping market is still new in the country (see Emmanuel, 2015). E-tailers would be able to determine the specific areas to channel their business resources mostly and understand their

target audience (consumers) better. Researchers would be able to identify salient issues, extract cogent variables, adopt appropriate and relevant research methodologies and theoretical models and then design cutting-edge conceptual frameworks that could yield better results. In addition, this chapter recommends that future research should adopt this model to conduct a study in different contexts, e.g., in the United Kingdom (UK), Ghana, Malaysia, the United States (US), etc using a qualitative perspective.

It may be necessary to extend the critical investigation into the exploitation of social networking sites by online retail stores to enhance cost-effective access online retail services. This chapter argues that social media platforms provide one of the most cost-effective promotion services to the online stores. In addition, publicizing and promoting products and services via social media ensures virtually the widest market coverage in the country (see FOTN, 2015). Finally, it may be necessary to direct future research attention on the correlation between consumer demographic characteristics and service quality.

CONCLUSION

Most of the respondents perceived e-shopping positively even though their acceptance of online shopping was rather moderate. However, their level of favorable perception of e-shopping could increase if, *ceteris paribus*, factors such as access and affordability of Internet services, technology use skills, prior e-shopping experience, trustworthiness and reliability of online stores were addressed.

Furthermore, the findings indicate that three out of the 10 factors investigated, namely Empathy ($M = 2.68$, $SD = .992$), Reliability Expectancy ($M = 2.67$, $SD = .971$) and Responsiveness Expectancy ($M = 2.61$, $SD = .941$) have been discovered to influence online shopping acceptance critically. Whereas, the influence of Facilitating Conditions ($M = 2.58$, $SD = 1.00$), Effort Expectancy ($M =$

2.52, SD = 1.01), Hedonic Motivation (M = 2.51, SD = 1.08) and Performance Expectancy (M = 2.43, SD = .911) was weak. The influence of Price Value (M = 2.26, SD = .601), Social Influence (M = 1.90, SD = .786) and Habit (M = 1.65, SD = .595) on e-shopping compliance was unimportant. These findings suggest that online stores' service quality (SQ) dimensions are the most important factors that affect online consumers' acceptance of e-shopping in Nigeria. Therefore, this chapter concludes consumers' perceptions of e-tailers' service quality influence e-shopping compliance more than cognitive perceptions do.

KEY TERMS AND DEFINITIONS

Acceptance: This term simply refers to an individual’s resolution to adopt a technology.

B2B: This acronym means business-to-business and it refers to online commercial activity directly between two or more business organizations (as opposed to between a firm and direct consumers).

B2C: This acronym means business-to-consumers and it refers to online commodity retail directly between a firm and consumers (as opposed to B2B).

Compliance: This term is a synonym of acceptance.

Consumers: This term refers to individuals that purchase products online for direct use (consumption).

E-Shopping: This term means electronic shopping and it refers to purchasing products and services online.

E-Tailers: This term means electronic retailers. It refers to business organizations that engage in retailing products online.

Online: This term can be defined from two major perspectives namely adjective and adverb. (1) Adjective: It refers to Internet-based applications such as website, web portal, e-data base, social networking sites and even cloud technology (such as Dropbox, Google Drive, etc.). (2) Adverb: It means performing a given task via the Internet or Internet-related platforms.

Enterprise Interoperability

E**Ejub Kajan***State University of Novi Pazar, Serbia*

INTRODUCTION

EC (Electronic Commerce) represents one of the major driving forces to build an electronic society. In the past enterprises faced with interoperability problems, first in the era of closed systems, later on in the infant era of open systems and ACME (A Company that Make Everything)-like vendor's solutions (Kajan, 2014). Since then, many interoperable frameworks have been suggested, developed and implemented; most of them are based on Web services and Semantic Web technologies. With the advent of globalization many organizations look for new partners to reach common goals to improve, for example, production rate, increase market share, refine supply chain, etc. Such new networked organizations are known as Virtual Enterprises (VEs). In a VE it is unlikely that any single partner will decide on the infrastructure, applications, and/or processes to be used. Instead, knowledge sharing around common goals and retaining the autonomy of each partner is crucial (Kajan, et. al., 2016).

In recent days enterprises are facing with a new challenge: everything is connected or it is going to be connected in the near future. In that movement social networking, networked things, smart objects, social communities of Web services, etc., are taking place as stated by Tan et al. "Currently, most social networks connect people or groups who expose similar interests or features. In the near future, we expect that such networks will connect other entities, such as software components, Web-based services, data resources, and workflows" (Tan et al., 2013).

As a consequence the new engineering discipline driven by the torrents of data available today

has born: the data science. Data is collected about anything, at any time and any place (van der Aalst, 2014). In such circumstances there is a lot of new heterogeneity issues between business processes, supported applications, data sources, events, and associated data on one side and different hardware, operating systems, database systems, network infrastructure, etc. on the other side, that make huge difficulties and barriers in achieving the full potential of EC. This article gives an overview of main challenges, obstacles, approaches and recent research efforts, and forecasts in order to overcome recent interoperability problems.

THE ISSUES AND CHALLENGES OF ENTERPRISE INTEROPERABILITY

The Web is the backbone of a new social era -a more open, global, ubiquitous, and pervasive platform. People, software, and things are part of a new era in which almost "everything" will be socially connected as shown in Figure 1. We refer to it as the *Social World*. The complexity of social world calls for mutual understanding of all entities involved. Besides many initiatives, ideas, and particular platform-to-platform solutions, connecting all by mutual understanding and self-learning capabilities is yet a big challenge (Dorloff & Kajan, 2012).

Interoperability is the ability of two or more systems or components to exchange information and use the information that has been exchanged in a useful way.¹ In the context of social enterprises (i.e., those that explore data from social world), interoperability is the ability of interactions (exchange of information and services) between

Figure 1. The social world

enterprise systems (Verginadis, 2011), but also to explore and exchange information of mutual interest gathered from social world. It has triggered the need of capturing the intrinsic characteristics of the business world (enterprises, their applications and stakeholders that may run various business processes) on the one side, and social and ubiquitous worlds on the other side, for bridging the gap between them. These goals have emphasized by (Romero and Vernadat, 2016) as “Enterprise Interoperability and Networking services will need to become a ‘commodity’ in order to support the building of a hyper-connected world and the seizing of its opportunities for industry (e.g. Industry 4.0)...”.

Most organizations are now modeled according to the principles of Service Oriented Architecture (SOA) for the sake of improving efficiency, agility, and response to changing market needs. SOA supports the integration of several enterprises into an entity usually known as a VE by exposing these organizations’ capabilities as services (Huhns & Singh, 2005). A VE possesses the following characteristics (Narendra, et al., 2013): (i) it is formed for a specific service-oriented process execution (for short- or long-term), and may dissolve once that execution is done; (ii) it is dependent on the nature of the interactions among the participating organizations; (iii) it is typically formed via a joint alignment of strategies among the participating organizations; and (iv) since the participating organizations are autonomous, conflicts would definitely arise.

The main goal of the VE is to provide business entities (BEs) with the ability to establish business collaborations in a way that their public business processes can interact with each other to exchange data. In a business scenario, BEs are usually loosely coupled; that means business processes require ad hoc integration from time to time. Such on-demand integration may experience many conflicts. Problems arise due to the heterogeneity between business processes and data involved, which are both different by nature on the one side and on the other side between underlying IT technologies, which are different by default. In EC, we re-characterize interoperability into A2A and B2B. They have much in common, but they are also different. Business processes inside an enterprise have their private and public parts, as shown in Figure 2. The private part is visible only inside a business entity interacting with other internal business processes whilst the public part acts inside the business entity but also takes place in B2B processes interacting with the public parts of business processes that belong to the other BE. A2A is an important mechanism for BEs in order to achieve business goals, but also serves as a flywheel of B2B efforts of that BE. As much as a BE reaches full A2A, i.e., it becomes a Zero Latency Enterprise (ZLE), i.e., its chances to have successful B2B relationships with other BEs increases (Kajan, 2010). Both A2A and B2B interoperability are victims of this heterogeneity. From that point of view, the main difference between them is the ability to control

Figure 2. The private and public parts of A2A and B2B

heterogeneity, which is much easier in a single business. In a B2B environment, where a large number of potential participants may exist, the autonomy of every BE how to run its own business is circumscribed. Thus B2B experiences face many more difficulties in interoperability than A2A.

Two Web technologies recently knocked on the doors of BEs, exemplified by two paradigms, Web 2.0, as a common name for Web of people using Internet and Web for people-to-people collaboration; and Internet of Things (IoT) that should, by nature, allow machine-to-machine communication, but also envisioning values to EC as well (Qin, et al., 2014). A visionary paper (Maamar, 2003) briefly set the target. Following that vision we set up the research roadmap for Enterprise 2.0 (Faci, et al., 2014), and made some experiments in the areas of business process design and management in social enterprises (Maamar, et al., 2013; Kajan, et al., 2014). These efforts among others gave an excellent opportunity to explore business process modeling, management, design, implementation and evaluation of VEs, and new possibilities to solve conflict resolution in business processes, as well (Maamar, et al., 2013). Ubiquitous Web gave many new opportunities, but also raised new

challenges to reach enterprise interoperability in A2A, B2B, and VE environments (Romero & Vernadat, 2016).

OBSTACLES IN ENTERPRISISE INTEROPERABILITY- PAST, PRESENT, AND FUTURE

Perhaps most readers of this article have forgotten or have never faced with the difficulties to reach any interoperable transaction in the era of closed systems. The era of open systems, first envisioned by OSI and definitively reached by Internet and Web, offers a lot of possibilities to reach enterprise interoperability on decent level. The most recognized and investigated obstacles for enterprise interoperability are semantics conflicts that may grow any time by any way, especially having in mind business relations on the fly (Kajan & Stoimenov, 2005). Conflicts may be of different types and at all levels of business collaboration. They may be caused either by data or business processes themselves, or business rules or business protocols, very often by all together.

Conflicts between data may appear either in data itself and/or in data schemas. At the data level, conflicts are caused by different representations and interpretations of same data (e.g., expressions, units, and precision) (Kim & Seo, 1991). At the schema level, conflicts are characterized by differences in logical structures and/or inconsistencies of metadata in the same application domain. Examples include names, entity identifiers, schema isomorphism, and other schema discrepancies (Sheth & Kashyap, 1992). Business data also suffers from semantic conflicts. Nevertheless, there are also specific conflicts that may occur between business data caused by different business documents, products and services catalogues and classification schemas as well. There are several reasons for this including, but not limited to, different document names, different

document structures, document elements and their representation, etc. These differences render BEs unable to establish collaboration between their business processes.

Semantic conflicts between business data are very complicated and differ from data integration in distributed heterogeneous databases. Research on business data (Ng, et al., 2000) shows that a typical product schema tree has two basic characteristics: shallowness (two or three levels) and bushiness (too many attributes, at the second level of a tree, most of them N:1 to the root of tree). There is also typically very limited knowledge about local schemas, a huge number of them, and fast evolution of these schemas.

At the business process level non-standardized business terminology, lack of common acceptable and understandable processes (grammar) and lack

Figure 3. Enterprise interoperability in the presence of ubiquitous Web

of common dialog rules (protocols). The problem arises from incompatibility of B2B protocols, i.e. from the heterogeneity of atomic transactions that appear in public part of a business process (Kajan, 2010). In a VE conflicts may be caused by different business rules that participating BEs may express depending of collaboration patterns among them (Kajan, et al., 2016).

By this end we have address the well known interoperability obstacles. When we come into the era of ubiquitous Web, where people, machines, software entities, communities of Web services, agents and multi-agents systems, smart objects, etc., offer opportunities to play important role in enterprise interoperability, a variety of new challenges have raised that should be solved to achieve full, conflict-free interoperability. But, new obstacles for enterprise interoperability have also risen. These include, but not limited to: dynamic nature of social and ubiquitous world, Big Data challenges, stakeholder's autonomy, privacy, sentiments-driven data, etc. A part of such heterogeneous environment has shown in Figure 3. The crossroads between M/W (middleware) and sensing/responding layer becomes one of the most research challenges for bringing enterprise interoperability into full potential.

BACKGROUND ON ENTERPRISE INTEROPERABILITY EFFORTS

The first serious requirement for data integration appeared in big enterprises whose systems consisted of many LANs mutually connected by either private or public infrastructures. In the 1980s, this requirement was satisfied by federated databases (Sheth & Larson, 1990). The problem with that approach was cost; it uses 1:1 relationship between every pair of databases involved in an integration process. Data Warehouses (DWs) offered a cheaper solution (Chaudhury & Dayal, 1997). Problem with DWs is their potential size because they are accumulating all the data during their use. Next step was represented by Data

Marts, (DM) introducing an interface data layer between query technologies and DWs. All of these three database technologies may be implemented in A2A, whilst for B2B they have no particular importance.

The big step forward for data integration in distributed environments has been made by eXtensible Markup Language (XML). The power of XML is based on its extensibility that allows users to create own domain-specific tags using Document Type Definition (DTD) or XML schema languages. XML has not been developed to define data semantics, thus its power is limited to common data syntax.

Another axis for data integration is semantic Web technologies (Berners-Lee, et al., 2001). The pool of human knowledge, as the Web was described by its inventor, has been transformed in recent years into a digital jungle with billions of documents in it. The idea behind the semantic Web is machine-readable Web supported with knowledge-oriented technologies such as Resource Description Framework (RDF) and Ontology Web Language (OWL). Although RDF is intended to give meaning to data by metadata and classes, respectively, it does not cover complete semantic requirements for interoperability. Here is the place where ontology deployment may play an important role.

In data integration, it is very common to use a combination of mediators and wrappers (Wiederhold, 1992), a three-layer architecture consisting of clients, middle tier and heterogeneous databases on the back layer. This integration architecture has been an active research area for almost twenty years. Examples include, but are not limited to, relational database integration (Papakonstantinou, et al., 1995; Yerneni, et al., 1999), B2B integration (Kajan & Stoimenov, 2005), integration of Deep Web data (Zhang, et al., 2012), etc.

The requirements for interoperability between processes also caused the development of middleware technologies. The first of them is Remote Procedure Call (RPC), the technology that allows clients to invoke remote procedure the same way as

local calls do (Birell & Nelson, 1984). The second generation of middleware technologies is based on distributed objects, the typical representatives of which are Common Object Request Broker Architecture (CORBA), Distributed Component Object Model (DCOM), and Enterprise Java Beans (EJB); the critical assessment on these technologies may be found in (Medjahed, et al., 2003).

Significant improvements in process interoperability have been made by Web Services, which has been considered as a key technology for the development of dynamic EC (Chen, et al., 2003). Web service environments are highly dynamic and distributed by nature, thus they required some requirements that should be met in order to achieve success of their composition. These requirements are identified at definition, selection and execution phases of Web services (Sheng et al., 2014). Although a lot of research on this promising technology has been conducted over the decade, the recent overview of these efforts (Sheng et al., 2014) shows that there is no maturity reached yet and it still contains some open issues that should be taken into account. These issues are related to composition that should be dependable, acceptable, autonomous and pervasive, but also to Restful services and data mashup capability, and security support as well.

Business process interoperability is one of the hot research topics for years. It includes analysis of potential technologies (Kajan, 2004; Medjahed, et al., 2003), Semantically Enabled Service-oriented Architectures (SESA) and modeling of choreography components for business process harmonization according to their structure and timing (Cardoso, 2007, Nacer & Aissani, 2014). Despite different approaches, all given research examples assume some kind of ontology deployment including ontology-based representation of product and services a given, for example in (Hepp, 2006; Hepp, 2008). There are several research prototypes of ontology-based middleware. Examples include, but not limited to, Toronto Virtual Enterprise (TOVE) (Fox & Gruninger, 1998), (Bremen University Semantic

Translator for Enhanced Retrieval (BUSTER) (Visser, 2004), Conflict Resolution Environment for Autonomous Mediation (CREAM) (Park & Ram, 2004), etc. Recent efforts that deploy ontologies into VE interoperability arena are motivated by variety of reasons. For example, Enterprise Competency Organization Schema (ECOS) aiming to standardize BE's profiles by shared ontology that may be used in pre-creation phase of VE in order to make the best choice in partner selection (Khilwaki, 2011). Wajid et al. (2013) work on a system to interplay between automatic recognition of business documents and human intervention by means of assisting mapping tool. From the viewpoint of semantic interoperability across VE, (Kajan, et al., 2016) proposes the use of goal based models for VEs in order to define up front the common goals of the VE and avoid ambiguities during enactment.

FUTURE RESEARCH DIRECTIONS

Towards Dynamic Knowledge-Based Interoperability

When we back to the fact that everything is going to be connected, if not yet, we are facing with, more or less, soft or hard, boundaries that exist among a variety of technology-driven networks, e.g. human-, service-, semantic-networks, networks of things and intelligent networks, as well. By this, the virtual world will be extended by a number of more complex physical objects acting in special environments. Collaborations in future real-time collaborations will take place between human beings, computers and facilities cooperating in different domains and environments. This enhances the still high heterogeneity of digital life and brings up new interoperability challenges. – drastically more objects to be identified and characterized, seamless connections between the Internet and radio networks, more complex feedback controlled systems, the need for more powerful and frameworks, concepts, models and monitoring systems.

Because of this heterogeneity, the restricted ability to control such complex interactions may become critical and new risks may arise. A big challenge will be to ensure visibility, common understanding and interoperability on all levels (Dorloff & Kajan, 2012). In consequence additional and even new standards and regulations on all levels of the Interoperability framework will be needed.

Although the research community continues to look into the Web from a technical and computational perspective, a *social perspective* has lately emerged as a direct result of the tremendous advances of Web 2.0 technologies. Web 2.0 technologies (e.g., REST and JSON) and Web 2.0 applications (e.g., LinkedIn, Tweeter, and Facebook) help enterprises tap into the social media so they can reach out to more customers, profile customers, gauge customers' satisfaction levels, and so on. Lee emphasized that the power of Web 2.0 does not rely on its software tools and techniques, but on data that Web 2.0 may bring within (Lee, 2011). He pointed out the six new business models behind Web 2.0 technologies, in which use of these technologies are primary tools to make revenue and survive on the market. In (Bonchi et al., 2011) special emphasis has given to data mining from social networks in order to improve business through Social CRM, recommender systems, collaboration with customers, production forecasting, expert finding, churn (loss of customers) analysis, etc. The Enterprise 2.0 (aka social enterprise) is the one that connects successfully business and social worlds in such way that accommodates the concerns of both the business community and the social community. Such connection requires a meet-in-the-middle environment capable to handle interactions between these two worlds (Buregio, et al., 2015). By now we will use a Social Machine-based approach for such environment (Buregio, et al., 2013). We believe that Social Machines actually represent a promising paradigm to deal with the complexity of this new emerging Web around us, and a practical way to explain each and every entity connected to it. We surely can use the concepts and instruments of

the existing Web 2.0 but we need more and higher sophisticated frameworks, methods knowledge and experience. A conceptual view to an extension of social machine with semantics capabilities using knowledge artifacts is given in (Buregio, et al., 2016). In that concept, each SSM can be viewed as a "knowledge-as-a-service" provider, once it offers different APIs that allow delivering insights into business and social artifacts it acts over. Such environment helps not only to bridge the gap between the business and social worlds but also to optimize the sharing and accessing of knowledge across the entire organization and stakeholders it interacts with. Bringing semantic to the social Web is a step towards intelligent networks that will allow intelligence-to-intelligence communications.

In the center of this concept are intelligent software agents, resident or mobile, armed with various AI skills and capable to act as independent self-proactive software artifacts. Since Kasbah, the first e-commerce agent marketplace (Chavez & Maes, 1996), up to day, research on agents, multiagent systems and agent communication languages is taking much interest in the research community, good overview of which may be found in (Wooldridge, 2009). Such agents are capable to build not only intelligent networks, but also to make a "self-active glue" that will be able to dynamically connect necessary pieces coming from other networks.

CONCLUSION

This article shows several lessons that we learned, which may be summarized as follows. Many efforts have been devoted to overcoming interoperability problems of any kind, but they have not reached their promise yet. Instead of unlimited interoperability inside and between *BEs*, the result was too many mutually incompatible "standards" that formed isolated areas of e-business seeking for new investments over and over again.

Recent research efforts are looking very promising. They are concentrating on two big goals: to provide middleware technologies and frameworks which are capable to act as self-acting dynamic artifacts at the time of invocation and to provide necessary semantic understanding between peers of any kind. Despite of well-defined goals and recent results, the whole thing is still under development. At least but not last, many business processes yet waiting to be socially modeled and managed. Is there a fiction or a forecast?

We believe that the whole idea based on knowledge-enabled self-acting artifacts is not yet another hip and that it will lead the Web and EC to their full potential. Let us finish this article with few visions given in the past. “Now we can imagine the world of people with active machines forming part of the infrastructure. We have only to express a request for bids, or make a bid, and machines will turn a small profit matching the two” wrote Tim Berners-Lee in the foreword of the book about Semantic Web (a.k.a. Web 3.0) (Fensel et al., 2003). For 25th anniversary of the Web San Murugesan cited a computer scientist Alan Kay: “The best way to predict a future is to invent it” emphasizing technological achievements on the Web and encouraging further application development towards more ubiquitous and smarter than current (Murugesan, 2014). Enterprise applications armed with full interoperability features will be there, for sure.

KEY TERMS AND DEFINITIONS

A2A (Application-to-Application): Process of data and application integration inside an enterprise in order to reach ZLE. Also known as EAI (Enterprise Application Integration) and EII (Enterprise Information Integration).

B2B (Business-to-Business): Type of EC where participating entities are enterprises at both sides. Nowadays, it may be thought as a third wave of EC, where *BEs* should be able to establish and handle their business relationship dynamically and seamlessly on demand.

Business Entity (BE): An enterprise, a part of an enterprise and/or its application that participate in A2A or B2B.

EC (Electronic Commerce): An emerging concept that describes the process of buying, selling, or exchanging data, services and products over the Internet.

Framework: A common template that has well defined functionality in order to solve a problem, e.g. interoperability, and precisely defined inputs and outputs intended for its communication with the external world.

Interoperability: An attribute given to systems, applications and data that assigns their ability to communicate with another systems, applications and data in a manner that they may exchange and mutually use that data.

Middleware: A dynamic self-organized layer, usually acting on the top of the transport layer, that provides uniformity between the lower layers of the framework (hardware, operating systems, etc.), which are different by default, and hides serious, natural discrepancies that exist among applications.

Virtual Enterprise (VE): A temporary alliance of BEs that come together to jointly fulfill common business goals.

ZLE (Zero Latency Enterprise): A *BE* that has been reached the full A2A integration so that there is no data latency between its own business processes.

Has Bitcoin Achieved the Characteristics of Money?

Donovan Peter Chan Wai Loon
University of Malaya, Malaysia

Sameer Kumar
University of Malaya, Malaysia

INTRODUCTION

In late 2013 and early 2014, the term bitcoin had made headlines in the global financial news. Designed and developed by Satoshi Nakamoto¹ (Nakamoto, 2008), this “virtual money” was propelled by cyber lobbyist and at the end of 2013 the exchange rate per bitcoin had multiplied more than five times over a space of several weeks. Supporters claim that the fundamental objective of bitcoin is to act as a substitute to the current payment systems and to allow dealings internationally, across currency denominations, without intervention of dominant bodies or central banks, and without the abuse of traditional financial institutions such as banks. According to followers of electronic currencies, government administrations regularly enforce unwanted controls and constraints and central banks may expedite oversupply of money leading to increased inflation. In addition, a large number of supporters also complain on the overpriced fees charged among other claimed exploitations done by banks. The dramatic rise in bitcoin’s value in November 2013 had triggered exceptional interest to it. The trading price of a bitcoin was only USD0.05 when it begun in 2010 and had reached and all time high exceeding USD1, 200.00 (Wood, 2013)

As the main role of Bitcoin’s creation is to function as an alternate form of currency that individuals can use to conduct transactions with each another without the interest of governing bodies such as banks, the main question that arises is

“how well can bitcoin serve the role of currency?” Money is commonly accepted to be a mechanism that functions as a medium of exchange, a unit of account, and a store of value (Halaburda & Gans, 2014). For the purpose of this paper we will be looking at how bitcoin has achieved these three functions.

BACKGROUND

Essentially, bitcoin is a peer-to-peer network version of e-cash that facilitates transactions between parties minus the proof requirement of an appointed third party; i.e. banks or financial institutions. This unit of network is denoted as bitcoin, which is considered by most to be the greatest digital currency to date (Brito & Castillo, 2013; Lo & Wang, 2014).

The advantages that bitcoin (Rogojanu & Badea, 2014) seems to offer are: 1) it is believed to be a completely decentralized method not linked with any predominant bodies, central banks, or recognized payment systems, which are ruled by banks and therefore it is thought to be less susceptible to exploitation or fraud; 2) it has pseudonymous characteristics; 3) it forces no direct charges on transactions and shows the possibility for transaction fees in general to be lesser. A person can use a bitcoin, by sending his or her account number which is the “public key” and a password which is the “private key” for authentication on the public transaction record,

known as the “block chain” (Reid & Harrigan, 2013) Certain individuals or “miners” will then use their computers processing power to authenticate if the transaction is real by solving a rigorous computational task also known as “finding the hash of a nonce” (Lo & Wang, 2014). As a payment for validating the transaction, the first person or party to provide the answer to the task will be compensated with a certain number of bitcoin, accumulating to the available stock of bitcoin and consequently generate money creation.

There is a process in the system, which routinely regulates the computational difficulty of validating transactions to guarantee that each transaction is normally verified within 10 minutes (Bamert, Decker, Elsen, Wattenhofer, & Welten, 2013). However, it is unavoidable that there are some uncertainties in the actual extent of time taken to verify each transaction. The same process also dictates the eventual quantity of bitcoin, which is estimated to be 21 million units by 2140.

BITCOIN AS MONEY

Medium of Exchange

While bitcoin has no inherent value, its price eventually depends on its practicality as a form of money in the consumer market. Indication of bitcoin’s mark in daily business is mostly hearsay, comprising of articles about individuals simply living by using bitcoin or estimations of big statistics of industries that are eager to agree to bitcoin. Majority of the high-ranking traders receiving bitcoins are led by companies in the software and hardware industry concentrated on marketing products dedicated to bitcoin applications and by exchange markets offering facilities to bitcoin investors.

Accurate understanding into the implementation of bitcoin can be acquired from data of the universal record of bitcoin transactions (Vander-vort, 2014). Data from numerous websites show that bitcoin daily transactions count has reached

capacities of tens of thousands but it is widely believed that most of these transactions comprise of activities between speculators, and only a few are actually used for trading of goods and services.

In March 2014, a co-founder of Coinbase Fred Ersham, the prominent digital wallet service, anticipated that 80% of activity on his site was associated with speculation. He also adds that 24,000 vendors are registered with Coinbase (Yermack, 2013). In a global market of billions of consumers, who make numerous commercial transactions everyday, bitcoin seems to have an extremely insignificant market presence.

Another barrier for bitcoin in developing as a general used means of exchange rises from the scarcity of obtaining new bitcoins. A user typically obtains bitcoins from vendors or virtual exchanges (Chowdhury & Mendelson, 2013). The user then needs to find a safe place to store the bitcoins such as digital wallets. Purchases of bitcoins cannot be usually made by credit card or via Paypal, however the user needs to connect his bank account or do a bank transfer to the exchange. The present bitcoin exchanges come with several issues such as low liquidity and to a certain extent execution risks. Another way is for users to mine bitcoin; but this is highly unlikely due to the huge capital investments needed to purchase supercomputers for the mining activity.

Lastly, bitcoin does not allow for users to receive goods and services from a vendor in advance without making prior payment for it. In most current online markets, users are constantly able to make purchases for items and services without money in hand. This is done through credit card facilities backed by the vendor or a third-party credit card company. Till date, there are no bitcoin related credit cards and the idea of such a facility seems to be unknown.

Unit of Account

Bitcoin is faced with a number of challenges for it to become a suitable unit of account. The first reason is due to its great instability. Bitcoin’s value

related to other currencies deviates significantly on daily basis. Merchants that deal with bitcoins often have to readjust prices, a habit that would be expensive to their businesses and complicating to the customer. In an economy that uses bitcoin as the main form of currency such a problem would not happen, but such environment is not available in today's society.

Another associated obstacle occurs due to the difference in "market values" that a bitcoin trades for at any certain period of time. This discrepancy of market prices, range from high to low estimations, causing a bitcoin's price to alter over several transactions within the same day. Many merchants are faced with the problem of changing market values of bitcoin and rely heavily on price aggregations, which does not take into account the merchants and customers actual cost of purchasing or selling a bitcoin at the current time. These circumstances are unimaginable in a present well-developed market as it clearly goes against the law of having a single price.

Possibly the greatest problem for bitcoin to become a generally used unit of account is its comparatively high price per unit. Bitcoin supporters more often than not, underestimate and overlook this important detail. At the present time of writing this paper, the average value of a bitcoin is USD247.88. This forces merchants to price goods with four or more decimals using the bitcoin (BTC) prices. Although supporters argue that the computations are simple and direct, it is difficult to adopt as no other currency in the world so far quotes prices for goods in this manner. General accounting software presently at use also adjusts its calculation to two decimal points for prices of goods. Advocates tend to disregard the failure of bitcoin to create prices that are familiar to customers. Sources are inclined to agree that the current computational data sets allow for bitcoins to be divided and have up to eight decimals places offering the prospect for a big enough number of units.

Store of Value

When money acts as a store of value, a person acquires the money and may choose to exchange it for goods or services at a later time to his convenience. When he does this, the person believes to get the same economic worth of what the money was when he had received it.

In the past, considering money as a store of value basically meant safeguarding it against theft. This was done by storing it in hidden places or by depositing it into a bank. Such approaches cannot be used to secure bitcoins as it does not have any physical form. Bitcoins must be kept inside computer software called "digital wallets", which safety has become a main concern of the bitcoin industry. Several digital wallet companies have sought the assistance of third-party insurers to provide some basic deposit insurance. This however does not exclude the customer from assuming the financial risk (Moore & Christin, 2013) should there be a breach in the security of both the digital wallet and insurance company.

If a customer discovers an effective means to keep and protect his bitcoins, he then has to deal with additional issues of handling the threat of bitcoin's high volatility. Figure 1 below depicts the volatility of the bitcoin-dollar exchange rate, using daily data gathered in 2013. For evaluation reasons the graph also depicts other major currencies and their volatilities of the exchange rates and the London Price of gold (Yermack, 2013). The major currencies used were Euro, Yen, British Pound, and Swiss Franc.

Bitcoin recorded the highest exchange rate volatility in 2013 with 142%. Exchange rate volatilities of major currencies were within the range of 7% to 12%. Gold, which is another credible source as a store of value had a volatility of 22% in 2013. In his analysis Yermack (2013) explains that majority of vastly traded shares have volatilities around 20% to 30%, and even high-risk shares seldom demonstrate a volatility as high as 100%.

Figure 1. Bitcoin volatility compared to major currencies and gold
(Yermack, 2013)

Based on Figure 1, it is possible to determine that keeping bitcoins even for a brief a period is dangerous, due to its inconsistency in acting as a store of value.

FUTURE RESEARCH DIRECTIONS

Most major currencies in global economy today are either supported by legal bodies or governments. Therefore, the question is “Who would have confidence in Bitcoin?” as it is not supported by either of the two entities mentioned above. However, people appear to put their trust in bitcoin, as the continuous buying of bitcoins is proportionate to keep it nearly at par with the US dollar. In this section, we will assess if this confidence is correct.

Confidence in Bitcoin

Most people tend to look at bitcoin as more of an investment. Similar to most other investments,

bitcoin is also vulnerable to unreasonable price bubbles and also ungrounded or grounded loss of confidence, which would cause the demand to fall and create a surplus in supply. Confidence in bitcoin may drop due to unanticipated fluctuations in the inflation imposed by software or hardware developers, a government crackdown, the creation of superior competing alternative currencies, or a deflationary spiral (Grinberg, 2011). Confidence may also drop due to technical issues; anonymity of the bitcoin system is exposed, theft of money, or if new transactions are denied by hackers or governments. Certain people put their faith in bitcoin as they trust that bitcoin is not governed by any central organization with the authority to expand the money supply above the inflation rate pre-programmed automatically into the software. Developers may however be able to do so, and even if it is done for a good purpose and with the consent of majority of bitcoin users, it could cause lost of confidence by many. In another aspect, the inflation rate could be increased tremendously that bitcoin suffers

from hyperinflation causing a steep drop of its value. A better rival currency (Barber, Boyen, Shi, & Uzun, 2012) could create a loss of confidence to bitcoin and reduce its value or cause the entire collapse. While bitcoin may be tough to shut down because of its distributed nature, government restrictions may yet be disastrous to the confidence level in bitcoin. Most users do not want to be associated let alone own a currency that is against the law. Hence, the future research must more look into ways and means as to how users and common people could have confidence in this new currency and treat it in at least similar to the traditional currencies.

Deflationary Spiral

Bitcoin may experience deflation that causes certain groups or even businesses to abandon bitcoin. This could possibly lead to a total meltdown of the system or mere depreciation in the value of bitcoin. As the higher limits of bitcoins is set at 21 million, bitcoins may become more treasured as time goes by as the supply of government supported currencies continue to grow. This statement is backed by opinions that people would source for commodities that are scarce and difficult to attain. However, when the prices of bitcoin take a downturn, miners of bitcoins may react by decreasing production leading to reduced demands and ultimately lower the value of it. The final result is underemployment and loss of capital. Consequently, bitcoin related industries might opt to end it and further limit bitcoin's reach. Future research could also look into ways that this e-currency remains stable. As mentioned in the section earlier, one of the biggest issues of bitcoin is its potential

Potential Technology Failures

Technological letdowns could also result in loss of confidence by users and discourage them from performing bitcoin transactions. Listed below are a few examples:

All bitcoin transactions are public. These transactions however are anonymous since there is nothing linking individuals or companies to the accounts in the transactions (Miers, Garman, Green, & Rubin, 2013). Occasionally, people do put their details online, which can be traced back to their virtual identities. There are possible techniques employing arithmetic calculations that can undo the anonymity of the system. Under unforeseen conditions and rapid exposure of this would be most detrimental to bitcoin's value. Just like physical money, bitcoin can be stolen or lost. Storing bitcoins in a personal computer is as risky as having large amounts of cash in a physical wallet. Users are generally advised to make backups and protect bitcoins through trusted online services such as digital wallet companies. Hackers employ an array of methods to conduct theft that target both individuals and large companies alike. Viruses or Trojans will conceal themselves in an individual's computer and steal the bitcoin data without the person even realizing before it's too late. Large-scale attacks can cause a confidence crisis amongst users of bitcoin. Even though bitcoin runs on a distributed network and usually has no specific point to breakdown, it is still prone to attacks by denial of service. Parties in the bitcoin mining system that have sufficient capabilities in computational power can efficiently stop any transaction from occurring. Gaining the required tools to conduct is fairly easy but expensive. This may be done by groups that stand to gain from the disruption of the bitcoin system such as hackers who want to hold bitcoin companies at ransom, governments who want stop bitcoin and even people who have other related interests. The future research has to look into ways and means to identify other potential failures and strengthen security.

CONCLUSION

The concept and innovation of bitcoin is ingenious. However for bitcoin to become more than just a

novelty and establish itself as a widely accepted currency, bitcoin must first have a more stable value. Bitcoin must also overcome the problems of its unconventional pricing mechanism, shortage of vendors who accept it, and the difficult way of obtaining bitcoins. Users of bitcoin will also need to have adequate computer knowledge when dealing with this currency thus creating an added barrier to a wider implementation of bitcoin.

It is uncertain to say what the future holds for bitcoin and its network. Nevertheless, a growing interest among society and scholars on the subject of virtual payment technologies and digital money's incredible potential on e-commerce warrants further research and development of understanding of this area.

KEY TERMS AND DEFINITIONS

Bitcoin: A global electronic currency without an intermediary (decentralized).

Block Chain: A public record of all bitcoin transactions mined since the beginning of bitcoin cryptocurrency.

Block: A new group of transactions. Blocks connect the transaction together.

Cold Storage: The safe keeping of private keys disconnected from the Internet.

Cryptocurrency: A non-printed currency produced by solving mathematical problems.

DoubleSpend: Sending bitcoins to two different parties at the same time. Bitcoin mechanism makes it almost impossible to double spend it.

Miner: A computer or group of computers that do bitcoin transactions (adding new transactions or verifying blocks created by other miners. Miners are rewarded with transactions fees.

Mining: Payment processing work for recording payments in the public ledger.

Private Key: Key (cryptographic system) known only to the user.

The Importance of Electronic Commerce in Modern Business

E**Kijpokin Kasemsap***Suan Sunandha Rajabhat University, Thailand*

INTRODUCTION

Electronic commerce (e-commerce) is the important Internet application that enhances the way of commercial transactions (Chang & Hu, 2012). E-commerce provides businesses to sell their products and services across the globe (Yapar, Bayrakdar, & Yapar, 2015). Given the tremendous success of the Internet and e-commerce in developed countries, emerging economies are quickly embracing information technology (IT) (Agarwal & Wu, 2015). The high efficiency, low trade costs, and simplified transaction process in e-commerce have changed manufacturers' operations, business, management models, and trade models (Lu & Liu, 2015). Multinational corporations often push their branches and suppliers to adopt e-commerce technology to connect with their global production network (Rahayu & Day, 2015).

E-commerce is beneficial to both business and consumer wise as payment and documentations can be completed with greater efficiency (Kasemsap, 2016a). The applications and opportunities for e-commerce are increasing (Huang, Lee, & Lee, 2009). Web technology and fast Internet access allow people to become more familiar with e-commerce (Jung, Cui, Eom, & Yeom, 2014). Information and communication technology (ICT) has fundamentally reshaped the way businesses and consumers can globally communicate, interact, and transact, thus generating the rapid growth of e-commerce (Pires, Stanton, & Salavrakos, 2010). E-commerce has made a significant impact on the traditionally vertical and horizontal relations of the supply chain, as well as the influenced social structure in modern

business (Chen, Yu, & Hsieh, 2013). Both virtual businesses and e-commerce operations enable organizations to have the fluid structures, modify the changing conditions, lower the expenses, and attain the new consumers (Gokmen, 2012).

This article aims to bridge the gap in the literature on the thorough literature consolidation of e-commerce. The extensive literatures of e-commerce provide a contribution to practitioners and researchers in order to maximize the business impact of e-commerce in modern business.

BACKGROUND

E-commerce has become an important factor in determining the future survival of organizations (Holsapple & Singh, 2000). E-commerce has substantial potential to foster the growth of small and medium-sized enterprises (SMEs) in developed and developing countries (Kurnia, Choudrie, Mahbubur, & Alzougool, 2015). Much of the existing literature on the SMEs' adoption of e-commerce technologies seeks to explain the e-commerce adoption behavior from the perspective of technology adoption, using theoretical frameworks, such as the Theory of Reasoned Action (Ajzen & Fishbein, 1975), the Theory of Planned Behavior (Ajzen, 1991), the Technology Acceptance Model (Davis, 1989), and the Diffusion of Innovation (DOI) (Rogers, 1995). Gibbs and Kraemer (2004) explained that the scope of e-commerce adoption across ten different countries is influenced by national factors such as government policy and e-commerce legislation.

DOI: 10.4018/978-1-5225-2255-3.ch243

The emergence of e-commerce presents the new challenges in understanding the consumers' switching intentions in the context of e-commerce in general and online auctions in particular (Lin, Cheng, Wang, & Chang, 2012). E-commerce consists of the purchasing and selling of products or services through electronic systems, such as computer networks and the Internet (Kasemsap, 2016b). E-commerce presents consumers with a convenient way of shopping outside of their local jurisdiction (Alm & Melnik, 2012). Online shopping seems to primarily reflect a desire for time efficiency on the part of the shopper (Anesbury, Nenycz-Thiel, Dawes, & Kennedy, 2016). Experience with online shopping directly increases the consumer's intention to use the Internet to buy products (Soopramanien, 2011).

E-commerce is defined as a reduction in the consumers' search costs (Goldmanis, Hortaçsu, Syverson, & Emre, 2010). E-commerce offers the possibility of accessing markets in a relatively low-risk, low-cost manner (Cloete & Doens, 2008). Several types of e-commerce including business-to-business (B2B), business-to-customer (B2C), and customer-to-customer (C2C) are common on the Internet (Shojaiemehr & Rafsanjani, 2013). E-commerce technologies, particularly those supporting B2B, exchange, include the Internet, e-mail, Electronic Data Interchange (EDI), Electronic Funds Transfer (EFT), and barcodes (Gunasekaran, Marri, McGaughey, & Nebhwani, 2002). Bharadwaj and Soni (2007) indicated that five parts of the e-commerce infrastructure include the flow of information, organizational image, reaction to customer needs, increased sales, and access to new markets.

The rapid development of IT enables an increasing number of consumers to search and book products online first and then to consume them in brick-and-mortar stores (Xiao & Dong, 2015). Existing studies have focused considerable attention on the factors regarding e-commerce adoption (Ghobakhloo, Arias-Aranda, & Benitez-Amado, 2011). The findings are classified into two categories (i.e., the strategic value of certain

IT to top managers and the factors that influence the adoption of IT) (Grandon & Pearson, 2004), emphasizing the importance of the perceived benefits, strategic commitment to e-commerce, external pressures, organizational readiness, information system characteristics, and e-commerce capabilities, among others (Hong & Zhu, 2006).

Several scholars have adopted the process perspective to explore the adoption of e-commerce (Lin, Huang, & Tseng, 2007). Such studies have adopted two alternative perspectives: a factor-oriented perspective (Kirwan, 2009) and a stage-oriented perspective (Rao, Metts, & Monge, 2003). Factor-oriented studies segment the adoption process into several stages, such as the initiation, decision and implementation stages, and investigate the facilitators and inhibitors in each stage (Cui & Pan, 2015). Stage-oriented studies focus on the adoption stages (e.g., presence, transaction portal integration, and enterprise combination) and investigate the features of each stage, such as communication channels and e-commerce functions (Cui & Pan, 2015).

PERSPECTIVES ON ELECTRONIC COMMERCE IN MODERN BUSINESS

This section emphasizes the overview of e-commerce and the importance of e-commerce in modern business.

Overview of Electronic Commerce

E-commerce has made considerable challenges into both large organizations and SMEs (Solaymani, Sohaili, & Yazdinejad, 2012). E-commerce is essential for enterprises because it improves their understanding of customer needs and of the products and services available in the global marketplace (Zhu, 2004). By conducting e-commerce, manufacturers can eliminate the distributors and wholesalers; optimize the internal processes; reduce the production period, inventory, and circulation (Chun, Rhee, Park, & Kim, 2011);

and obtain the higher margins (Laudon & Traver, 2009). Although some manufacturers, such as Dell, General Electric, and Estee Lauder (Yan & Pei, 2010), have achieved tangible improvements in their operational efficiency and revenue generation by adopting e-commerce, some firms have been less successful. Researchers and practitioners have struggled to determine the optimal conditions for the adoption of e-commerce by manufacturers (Oh, Cruickshank, & Anderson, 2009).

Privacy preservation relies on the good faith of individuals and organizations that gather data on the customers in an open electronic environment, such as the Internet (Aimeur, Brassard, Fernandez, & Onana, 2008). For e-commerce to reach its full potential, consumers must have the effective protection when shopping online, and their primary rights must be adequately protected (Dahiyat, 2011). One of the foundations of e-commerce is trust (van Baal, 2015). The importance of trust in building and maintaining the consumer relationships in the online environment is widely accepted in the information system literature (Cheung & Lee, 2006). Trust plays an important role in the formation of dependent relationships represented by online transactions (Li, Pieńkowski, van Moorsel, & Smith, 2012).

Trust has been recognized as a main factor in promoting e-commerce (Son, Narasimhan, & Riggins, 2005). The increasing popularity of open standards in e-commerce demands more research on generalized trust (Qu, Pinsonneault, Tomiuk, Wang, & Liu, 2015). Zaheer and Venkatraman (1994) investigated the electronic linkages in the insurance industry and found that the insurance agencies' trust in the carrier practically increases their business toward the carrier over electronic channels. Hart and Saunders (1998) stated that suppliers' trust in customers increases the suppliers' use of EDI for diverse functions (e.g., inventory advice and order status report). Klein et al. (2007) indicated that mutual trust between trading partners increases IT customization for supply chain coordination and improves the strategic information sharing about capacity planning, production schedule, and marketing strategies.

In e-commerce environments, the reputation of sellers is a crucial issue to the potential buyers in making decisions (Zhang, Wang, & Zhang, 2014). Because of the importance of reputation management, a variety of reputation management models that can be utilized in many e-commerce markets have been developed during the past several years (Zhou, Dresner, & Windle, 2008). For many e-commerce models, reputation management has become one of the critical factors that restrict their development (Rice, 2012). In the electronic business (e-business) market, merchants' reputation can help consumers reduce information asymmetry and increase their acceptance of e-commerce (Ruohomaa & Kutvonen, 2005).

Importance of Electronic Commerce in Modern Business

The increasing popularity of e-commerce is apparent (Spremic & Hlupic, 2007). Firms should employ e-commerce to compete in the global competition of the 21st century (Wu & Fang, 2011). The Internet and related technologies have vastly expanded the variety of products that can be profitably promoted and sold by online retailers (Hinz & Eckert, 2010). To make business organizations grow in the rapidly changing environment, managers must understand the knowledge of e-commerce and keep paying attention to e-commerce development (Shiau & Dwivedi, 2013). Business organizations need their information system and knowledge management to offer the e-commerce solutions (Sharma, Gupta, & Wickramasinghe, 2006).

Internet has a tremendous impact on how companies do business (Frank & Lange, 2007). The use of the Internet as the additional sales channel offers the traditional retailers opportunities to reach the expanded markets while improving the efficiency of their operations (Xia & Zhang, 2010). Firm ability in conducting transaction and collaboration with business partners over electronic channels (e.g., B2B e-commerce) can have the strategic impact on firm performance (Wong, Lai, & Cheng, 2011). B2C e-commerce fundamentally alters the

structure of those transaction costs relevant to the IT structure and the brand architecture in global marketing (Treiblmaier & Strebing, 2008).

The adoption of e-commerce technologies enables SMEs to access larger markets without expanding their physical presence (Quaddus & Hofmeyer, 2007). E-commerce technologies have a strong appeal to SME retailers as e-commerce can make geographic locations and time irrelevant (Premkumar & Roberts, 1999). Due to the impacts of e-commerce technologies on SMEs, e-commerce technologies have become the significant entities of attention within business and entrepreneurship literature (Peltier, Zhao, & Schibrowsky, 2012).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of e-commerce will provide the potential opportunities for future research. Mobile commerce is the business that is conducted on the Internet through the use of mobile phones or other handheld electronic devices (Kasemsap, 2016c). With the rapid growth and innovations witnessed in the mobile industry, the communication field has greatly transformed. Business communication has greatly eased with the advent of mobile communication. Business communication enables colleagues or business partners to discuss business without necessarily holding meetings. The Internet-enabled phones give access to social media platforms, such as Facebook and Twitter, from anywhere across the globe.

The use of social media improves effective communication, increases thought leadership, enhances sales, and provides better customer service (Kasemsap, 2016d). Professional and business applications of social media platforms can enhance business performance toward reaching strategic goals in the digital age (Kasemsap,

2017a). Web mining is the application of data mining techniques to discover the interesting patterns from web data in order to better serve the needs of web-based multifaceted applications (Kasemsap, 2017b). An examination of linkages among e-commerce, mobile commerce, mobile communication, business communication, social media, and web mining in modern business would seem to be viable for future research efforts.

CONCLUSION

This article highlighted the overview of e-commerce and the importance of e-commerce in modern business. E-commerce consists of the purchasing and selling of products or services through electronic systems, such as computer networks and the Internet. In this modern world of technology, e-commerce becomes a very significant option for many businesses as there are lots of companies that are interested in developing their online stores. E-commerce becomes one of the preferred ways of online shopping as they enjoy their online because of its easiness and convenience.

Because of its convenience, consumers can save their lots of time as well as money by searching their products easily and making purchasing online. The performance of e-commerce is critical for modern organizations that seek to serve suppliers and customers, increase business performance, strengthen competitiveness, and gain sustainable competitive advantage in modern business. Thus, it is urgent for modern organizations to promote their e-commerce and develop a strategic plan to regularly investigate their practical improvements toward satisfying customer requirements. Applying e-commerce has the potential to enhance organizational performance and gain sustainable competitive advantage in modern business.

KEY TERMS AND DEFINITIONS

Business: The activity of buying and selling commodities, products, or services.

Competitive Advantage: A superiority gained by an organization when it can provide the same value as its competitors but at a lower price, or can

charge the higher prices by providing the greater value through differentiation.

Electronic Commerce: The activities that relate to the buying and selling of products and services over the Internet.

Information Technology: The development, installation, and implementation of computer systems and applications.

Internet: The worldwide computer network that provides information on many subjects and enables users to exchange the messages.

Marketing: The strategic functions involve in identifying and appealing to the particular groups of consumers, often including activities, such as advertising, branding, pricing, and sales.

Technology: The branch of knowledge that deals with the creation and use of technical methods and their interrelation with life, society, and the environment.

Improving Competencies for the Courier Service Industry in Malaysia

Hoo Yee Hui

Universiti Tunku Abdul Rahman, Malaysia

Yudi Fernando

Universiti Malaysia Pahang, Malaysia

INTRODUCTION

Begun around the year 2000, globalization is being powered by individuals and smaller organizations. Emergence of e-commerce enables the individuals and smaller organizations to do business in a more effectiveness and efficiency way (Bowersox et al., 2013). They increasingly rely on courier services that can complement and contribute to their logistics operation particularly in Asia market due to its high population.

It is crucial for a business to reassess their competencies to operate in a competitive global working environment which is highly volatile and rapidly change. Subsequently, the supply chain is facing a paradigm change in the e-business environment. A company supply chain in an e-business environment can be very complicated typically in Asia Market due to Asia Market is made up of many countries which is vary in culture, religion, political system, legal systems, language and stage of economic development. The use of internet and advancement in technologies enable e-commerce to quickly emerge in courier service industry, linking enterprises, associations, governments and individuals together. The usage of internet has changed the industry strategy in conducting business.

The aim of this chapter is, therefore, to explore the literature on improving competencies for the courier service industry in Malaysia. The competencies of courier services as the ability of third party (3PL) logistics operator to smooth

the supply chain in e-commerce. The focus of the study is not how courier services competencies is generated within an e-commerce environment in Malaysia, but rather on how such competencies manifest itself, and able to ultimately influence the competencies for the Courier Service Industry in Malaysia. Additionally, this study is intended to help shape the future of courier services as a professional entity in the business environment.

BACKGROUND

Globalization affects the way of doing business today. Many industries experienced deregulation, deconsolidation, re-engineering, downsizing, and organization restructuring to meet the need for efficiency in a fast-paced operation with unpredictable supply pattern (Ling, 2014; Sheffi, 2012; Grant et al., 2006).

E-commerce has opened up an utterly new market for players in logistics. In the year 2012, total population in Malaysia has reached 28.7 million and the internet users are 17.7million accounted 65.8% of the population. Among the users of internet in Malaysia, there are 30% of the people who are e-shoppers that engage in purchasing goods and services from various entities on the web (Malaysian Communications and Multimedia Commission, 2012).

Besides that, business of courier services has been stimulated by the development of e-commerce in terms of the growth in parcels volume and in

home delivery. There is a tremendous increase in sales orders delivered by e-commerce companies that accomplish via courier companies, which has resulted in the rapid growth in this niche segment as well as the increase in the struggle for a greater market share in this sector (Hoo et al. 2014).

Sheffi (2012) defined logistics clusters as one of the strategies to support existing local industries, these clusters include third party logistics services providers (3PLs), transportation carriers, warehousing companies, freight forwarders, retailers, distributors, manufacturer; and the operations of companies for whom logistics is a large part of their cost. Courier service is operationally distinguished from the ordinary mail services. It plays a role as third party logistics services providers (3PLs) in Malaysia logistics clusters.

The logistics clusters have been recognized as one of the sectors attain global competitiveness in the Ninth Malaysia Plan and Third Industrial Plan (IMP3) (Khalid, 2009). Unfortunately, the Chairman of Asia Logistics Council, Sri Abdul Rahman Mamat declared that logistics sector is the weakest amongst the four pillars of international trade namely finance, commerce, insurance and logistics in Malaysia (Bernama, 2013).

PROBLEM STATEMENT

The courier services industry plays a key role in e-commerce activities by meeting the delivery fulfillment in the right time, to the right person, at the right place. In a study conducted by Malaysian Communication and Multimedia Commission (MCMC), result shown that the customer satisfaction index towards courier service in 4th quarter of year 2010 is 3.74 from a scale of 1 (total dissatisfaction) to 5 (total satisfaction). According to the Industry Performance report for the year 2012 provided by Malaysian Communication and Multimedia Commission, the quality goal achieved is only 69% which is lower than the expected quality goal, more than 80%.

It is a challenge for courier service providers when facing online order soars, fulfilling customers' order become more complex. Because of the recent increase and focus on e-commerce, without some movement toward the establishment of professional principles for practitioners in this field, there will continue to be a lack of awareness and acknowledgement about the specialized and unique skills and knowledge inherent in the practice of courier service industry.

RESEARCH QUESTIONS

This study seeks to uncover the professional skills and competencies for individuals who work in courier services industry. The main research question is: What are the competencies of courier services in Malaysia? The following two questions will be examined: (1) What are the required professional skills for courier services practitioners? (2) What are the most critical competencies factors in courier services?

OBJECTIVE OF THE STUDY

The learning purposes were listed as below:

1. To identify the competencies that marks a professional in courier services industry.
2. To investigate the critical competitive factors for the courier services industry.

LITERATURE REVIEW

Logistics secured a prominent role as it provides the backbone to facilitate the international trade. With the increase of the global competition and rapid progress of the IT technology, the emergence of e-commerce has spurred the demand for courier service in order to facilitate the delivery of merchandise purchased online.

Courier service is operationally distinguished from the ordinary mail services by some features including speed, security, tracking, signature, specialization and individualization of express services, and swift delivery times, which are optional for daily mail services (Hoo et al., 2014). Besides that, courier service plays an important role in the success of e-tailing business. It offered one stop solution to e-retailer by providing services from warehouse management to goods delivery.

In the consumers' perspective, they look for courier service providers that are able to offer same day delivery. For example, Amazon.com order fulfillment goal is to ship orders on the same day they are placed by the customers (Grant et al. 2006). However, in the e-tailing market, customer prefers free shipping while the retailers tend not to choose faster shipping option because it is expensive for them. E-tailing is directly derived from the word "retailing". Chandra & Sunitha (2012) defined e-tailing as retailing conducted online, over the internet. A survey shown that package shipped per order in e-tailing market increased from 2.3 per order in year 2014 to 2.6 per order in year 2015. (Stevens, L., 2016). This phenomena result a longer shipping time due to longer transit time for courier service provider to reach its receiver.

According to Malaysian Communications and Multimedia Commission (MCMC), there are total 112 licensed courier companies in Malaysia in year 2010. The number of active courier companies only accounted 35 and 28 of them are members of AMEC. AMEC members account for about 85% of the entire value of the Malaysian express market. The number of branches in courier services industry in Malaysia increased from 240 branches in the year 2010 to 266 branches in the year 2013 (Postal and Courier services, 2013) indicated that the demand on this service had increase significantly.

Unlike other transportation service provider in Malaysia's Logistics Cluster which is under contract to local authorities, Land Public Transport Commission (SPAD) and Road Transport Department (JPJ), the courier service industry in

Malaysia is governed by the Malaysian Communications and Multimedia Commission (MCMC) under Law of Malaysia Act 741. Under the Proposed Industry Development Plan for 2015 under MCMC, research on e-commerce impact on Postal and Courier Industry served as one of the events to be launched recently (AMEC, 2015).

Under the Law of Malaysia Act 741, Postal Service Act 2012 is used to regulate the freight rate, license provision, as well as customer protection. Although the rates are being regulated, the act does not standardize the services offered by the courier services providers in Malaysia. This had made courier service industry a dynamic business entities in Malaysia logistics cluster. Wide range of logistics services can be offered by courier services including but not limited to mailing room services, break bulk, customized logistics solutions, warehousing, and shipping services through its fourth party logistics service provider.

In another hand, the launching of National Broadband Initiatives (NBI) in Malaysia encourages its citizen to use e-commerce services for their daily economies activities. Many e-commerce service providers such as *Groupon.com*, *Ensogo.com*, *11 street.com*, *Lazada.com* in Malaysia had started to react on this phenomena and offered logistics related job to ensure the smooth operation of its e-commerce activities (Jobstreet, 2015). Also, the job responsibility of logistics manager in *11 street.com* is to manage the logistics and deliver in Market place model "dropship" (Jobstreet, 2015).

E-commerce is a key driver in the growth of courier service as more and more people buying and selling through the internet (Alminnourliza and Osman, 2012). The development of e-commerce had break the sales limited in time and space, and plays an important role in the construction of information system, logistics, capital flow and information flow (Chen, Q. & Zhang, N., 2014).

Over the past five years (2010-2014), Malaysia's e-commerce market size has seen 31% increase in compound annual growth rate (CAGR) and emerging as the third country that recorded

the highest percentage of Internet users (67%) after Singapore and Brunei in Southeast Asia. The emerging of e-commerce causing the growth in logistic industry, especially the courier segment has seen exponential growth over the past one year. For instance, courier service contributed 60% of POS Malaysia's total earnings in year 2015, as compared to 41% in year 2014 (Retail Asia, 2016).

Viswanadham, Kumar and Gaonkar (2002, p. 1503) defined three modes of e-commerce order fulfillment which are (1) dedicated in-house fulfillment, (2) outsourcing the fulfillment to a third party which offered one stop solution to e-commerce companies as well as maintains the inventory in the warehouse, and (3) supplier drop shipping the items to the customer whereby the dropshipper orders goods from its own supplier and manages its own warehouse and transportation system. Unlike the case in outsourcing, the goods in the warehouse are under the ownership of the dropshipper.

Development of e-commerce causes modifications to logistics chain management strategies and methods of flow control which cover both the process of handling the online and offline sales channel. Initially a niche service, courier services became an accessible service to wider categories of clients coupled with the increase infrastructure of developing countries and rural areas (Georgescu, 2012).

Logistics infrastructure is required to sustain a country's competitive advantage in long term. Serbat & Harun (2011) analyzed that the logistics competencies are used to obtain the competitive advantage by countries that are integrated to global economy. They found that logistics infrastructure is the most effective ways in discriminating between high and low competitive countries which include all the modes of transportation and Information and Communication Technologies (ICT).

Employee skill, experience and knowledge are the intangible assets in the organization. To increase the capability of employees and ensure quality service provide to customer in today's competitive market, job performance management

became an important task for organization. One of the tools to evaluate job performance is using job appraisal. Beatson et al. (2008, p. 170) describe job performance as the following:

When staff enjoys their jobs they are more likely to value the firm's customers and want to ensure that these customers are happy with the service they receive. The way that these staff can do this is by delivering good service and fulfilling customers' needs.

Hence, job performance presented in delivering good service and fulfilling customer needs.

In the study conducted by Gupta and Sharma (2009) on the factors influence job satisfaction level in public sector organizations, various factors influence job satisfaction had been identified and classified into two categories which are environmental factors and physical factors. The following factors are found in environmental factors:

1. Leadership and planning in the organization,
2. Individual participation,
3. Recognition and rewards,
4. Team work and cooperation,
5. Training program.

Result shown that training program was the most important factor as it enabled employees to keep themselves well-equipped with organization change.

Researchers had identified three competitive factors for supply chain strategy which are time, cost and quality under competitive profile (Harrison et al., 2014). Time refers to the order lead time or response time. Cost refers to the total cost of supply and underpins the price changed. Quality refers to the delivery reliability.

Shang and Chin (2012) discovered the importance of maritime service attributes such as transit time, on-time pick up and delivery, reliability of delivery are categorized under reliability of shippers' requirement. Not only that, Jaiswal (2008) believe that reliability is the most vital aspect of

service quality attributes especially for freight forwarders involving in the service sector. Hence, reliability is considered to be a crucial factor for the courier service competencies improving.

Ling (2014) explained further on firm's competitive priorities is determined by its four long-term structural decisions: facility, capacity, technology, and vertical integration, as well as by its four infrastructural decisions: workforce, quality, production planning and control, and organization.

Information technology is one of the important factors for courier service to engage with customer especially dealing with e-commerce transaction. Information technology was defined as the new technology to improve the efficiency of logistics operation (Huang, et al., 2013). Investment and adoption of information technology has become a crucial factor to supply chain efficiency and effectiveness in globalization era.

However, new information and technologies must be adopted by companies in order to integrate the supply chain process. These technologies are including information system such as warehouse management system (WMS), integrated business management systems and transportation management systems (TMS). Never the less, the communication technologies such as radio identification tags (RFID) and global positioning system (GPS) also helps the courier service provider to shorter the transit time and track consignment effectively (Roy, j., 2010). A study conducted by Mohamed (2008) found that using latest technologies to automated tracking of consignments as well as delivery status remain challenges.

Integration of e-commerce and courier service is a key online business strategy which enables the e-retailers to deliver convenient and seamless online shopping experience that customers expect and deserve. Courier services providers plays an important role in the supply chain of e-commerce as they are the last "node" in the e-commerce supply chain. The focus on competencies in courier services industry will spurred innovation, attracting more talent and more money that contributed to the growth of the cluster.

METHODOLOGY

The study applies Delphi methodology to identify the competencies in courier services industry. Delphi research methodology was selected for this study because of its ability to gain consensus about the required professional skills and knowledge of courier service practitioners.

The Delphi method is defined as a method for structuring a group communication process in allowing a group of individuals to deal with a complex problem (Cole, 2008, Linstone & Turoff, 1975). This method was used to identify and assess the required professional competencies for successful performance of courier services professionals.

FUTURE RESEARCH DIRECTIONS

Although there are some increases in the research of the subject of this study within Malaysia context, however, the research in improving competencies for the courier service industry in Malaysia have not reached an optimum level as compared to the Asian counterparts. This study contributes to e-business' and courier services' owners by unveiling a better understandings in Malaysia context toward the competencies that would give the e-commerce and courier service industry a huge boost.

Throughout the literature of this study, it is proposed that courier service providers should pay more attention to those key factors possess a positive correlation that not only enhance the growth of e-commerce industry but also boost the development of courier service sector. Subsequently, success in e-commerce and courier service can be promisingly achieved since the business environment is changing constantly and customer demand is evolving.

CONCLUSION

The evolution of e-commerce will fascinate people to shop online and acquire their desirable goods from other parts of the worlds. This phenomenon will arouse the demand for courier service. Handling of courier service from the delivery process of merchandise purchased online to the arrival of goods at the door steps of online shoppers needed to be expedited.

KEY TERMS AND DEFINITIONS

Courier Service: A third party logistics services provider whereby its primary services are to receive shipments and to deliver shipments in a short transit timeframe.

Delphi Method: One of the research method usually applied by researchers on a complex problem with limited research respondents.

Dropshipper: A sender who orders goods from its own supplier and owned a fully control in its warehouse and transportation system.

E-Shoppers: Consumers who obtain goods and services from various entities without geographical limitation through internet platform.

E-Tailing: Retail business which is conducted online.

Logistics Clusters: A logistics strategic to improve and promote the existing local industries.

Logistics Competencies: The ability of a logistics service provider to do a job in an effectiveness and efficiency way.

E

New Advances in E-Commerce

Khaled Ahmed Nagaty

The British University in Egypt, Egypt

INTRODUCTION

Advances in computer architecture and communication technology have led to introduction of global, dynamic and intelligent e-business models and new tools for doing e-commerce. These models use artificial intelligence techniques and web2 technologies to perform online transactions between businesses and customers. As the number of clients over the Internet grows exponentially enhanced intelligent e-business models are needed to efficiently respond to clients with an optimum selection for their requests. Agent based e-business models use intelligent agents, mobile agents, evolutionary agents, rational agents, data-mining agents to develop agent-based e-commerce models. Recommender systems provide intelligent assistance to online customers is CBR-based or collaborative filtering based e-business models. In B2C models there are a large numbers of buyers and sellers where buyers specify their preferences and sellers specify their products and selling prices. The major role of AI techniques in B2C e-commerce is to come up with the best match between a buyer and seller. Examples of e-commerce systems in B2C using AI techniques are product selection and recommendation, negotiation and auction systems. In B2B the major role of AI techniques is supply chain management to help clients taking the right decisions. Modern tools used by intelligent E-commerce models include: algorithmic trading, decentralized autonomous corporations (DAC), crypto-currency systems, smart contracts, Internet of Things, cloud computing and big data analytics.

BACKGROUND

Intelligent Techniques

Intelligent techniques in E-commerce include:

Intelligent Agents

They are personalized software that function independently and use machine-learning algorithms to analyze data, adapt to their environment in order to achieve the goals on behalf of users. Main agents can use sub-agents to work under their supervision to achieve smaller tasks to help main agents achieve their pre-written goals. These agents can surf the Internet gathering information, searching e-market places looking for products and services satisfying users' preferences. With the help of intelligent agents customers can enter e-negotiations and take part in e-auctions. According to (Nwana, 1996), the intelligent agents important features include:

1. **Autonomy:** Agents achieve their goals independently and act proactively without human intervention.
2. **Cooperation:** Agents communicate with each other and negotiate on certain issues.
3. **Learning:** Agents are able to learn, react or interact with their environment and with other agents.

Intelligent agents allow sellers to track demand and market shares, perform knowledge mining, negotiate and learn from collaboration with buyer agents. Seller agents can gain money by selling

services, they may create children that may either survive or die depending on whether they can get enough business. Broker agents, provider agents and merchant agents sell products and services required by sellers while comparison shopping agents are required for buyers to comparison shop (Sinmao, 1999). These types of agents get the required information from retailers' web sites using semantic web.

Types of intelligent agents include:

1. **Rational Agents:** They are autonomous computer programs that are capable of a goal directed behavior (Russell et al, 2003). The main goal of rational agents is to autonomously select the optimal outcome from possible preferences in a given situation. To achieve this goal the rational agents collect information about their environment which may be obtained from past experiences, they take actions considering obligations and duties then they evaluate the outcome to decide whether the final decision is the optimum one or not. If the final result is not optimum the rational agents adjust their behavior to improve results in the future.
2. **Evolutionary Agents:** They are agents that gain new knowledge from self-reasoning and through knowledge exchange with other agents. Evolutionary agents share information and knowledge with each other within a multi-agent environment regardless of their structures or objectives. The main task for each evolutionary agent is to fulfill one or more of its own goals. Agents are selected for growth from the current population to go into the mating pool. This mating pool is the basis for the next population. The growth mechanism is based on learning mechanism, fuzzy reasoning and ontological reasoning. The most fitting agent is selected based on a self-organizing map.
3. **Data Mining Agents:** They are agents designed to find specific data types and identifying patterns among this data. They generate alerts to organizations if any altera-

tion in the trend paradigm is discovered so effective strategies can be implemented to gain from this alteration or reduce its damage. Data mining agents perform one or more specific tasks, for example they can be programmed to monitor stock prices for a specific range of companies and alerting their users if significant aberrations from historical trends are discovered.

CBR Technique (Prasad, 1995)

Content based reasoning is a problem solving technique that retrieves solutions for previous similar cases from the case-base and adapt them to solve new problems. Each case has two parts: specification part and solution part. The specifications part describes the symptoms of the problem while the solution part describes the causes of this fault. CBR plays an important role in e-commerce applications for product recommendations by using context-sensitive information related to products to help users take the right decision quickly (Kumar et al., 2005). Content-based techniques make use of textual annotations describing products obtained from e-commerce websites (Abbattista, et al., 2002).

CBR works as follows:

1. Take customer preferences. Customers preferences may vague or rate their preferences ranging from 'must have' to 'not important'.
2. Retrieve products with similar offers from case base and submit them to the customer.
3. Customer may accept a similar offer or quit the process if he is no longer interested.
4. Customer may modify his preferences and go to step (ii). Similarity or disparity measures between two products are to identify similar products. Weighted Euclidean distance measure is used to retrieve the most similar product (Wettschereck and Aha, 1995). As an example a CBR-based recommender system in the sports domain is presented in (Prasad and Clementi 2002). Figure 1 shows a CBR e-commerce system.

Figure 1. A CBR e-commerce system
Prasad, 1995.

Recently CBR has a significant contribution in developing web-based intelligent systems. Figure 2 is the general architecture of Web-based CBR systems.

ACF Technique (Hayes et al, 2001)

An automated collaborative filtering that is similar to case base reasoning (CBR). While the CBR

Figure 2. General architecture of web-based CBR system
Zhaohao Sun, 2004.

produces a solution the ACF produces recommended components for the target user profile. It is a method to make automatic predictions (filtering) about a user's preference by collecting information about many users' preferences (collaboration). In ACF based recommender web sites, each ACF customer profile contains records about the historical customer's consumptions of items with either explicit or implicit ratings. An ACF case is an incomplete one – it is essentially one row in the utility matrix which is usually quite sparsely populated. ACF main goal is case completion which is an incremental enhancement of the user profile based on user's feedback. When a new user access the E-commerce website, the system uses this information to match the user's preferences with the database of preferences, in order to retrieve a user profile with a preference class closely matches the new user's preferences and extract completion information for the new case profile which is then submitted to the new user. Products that satisfy new user's preferences are then recommended to the new user (Sarwar et al., 2002). ACF has an indefinite iterative recommendation cycle where items recommended for inclusion in a user's profile are determined by the feedback input from this user. The recommendation cycle includes three phases: the *retrieve* phase where similar profiles are retrieved, the *reuse* phase and the *revise* phase.

GBR Approach (Burke 2000)

A goal-based reasoning approach used to search for products similar to those already known to the user. There are always some standard goals for each product domain, where a similarity metric between two products is measured regarding these goals. Different users might have different rankings of goals or different goals altogether. For each goal, a similarity metric between pairs of products defines how closely those two products with respect to that goal. Interaction between goals should be considered and combination of metrics is used to achieve ranking of products.

Supply Chain Management (SCM) is a key element for successful B2B e-commerce. With the exponential growth of Internet users e-commerce enterprises redesign their business models as they are moving to e-commerce environment (Fenstermacher and Zeng, 1999). Most of AI-based SCM problem solvers are agent based where each agent is responsible for one or more activities of the SCM (Prasad, 2003).

Modern Tools

Intelligent E-commerce models based on the above intelligent techniques are adapting to the emerged modern tools namely smart phones and cloud computing. However, tools such as big data analytics and social media are used to provide E-commerce intelligent models with insights required to improve the performance of these models. In this section, the most prominent modern tools and their influence on intelligent E-commerce models are discussed.

Algorithmic Trading

Also known as algo-trading, black box trading or automated trading where fast computers and complex mathematical models are used to automate one or more of the trading process stages. They benefit from statistical patterns within or across financial markets to capture odd prices, detect and exploit rival strategies to optimally execute a defined set of instructions for placing trades to generate profits either by costs saving, client commissions or proprietary trading at a very high speed and frequency that are beyond the capabilities of human minds (Giuseppe Nuti et al., 2011). Figure 3 shows the principal components of an algo-trading system and the order at which they process.

The algorithmic trading system is composed of the pre-trade analysis component, trading signal generation and trade execution components. The pre-trade analysis encompasses any system that uses financial data and involves intelligent

Figure 3. Algorithmic trading components
As adapted from Giuseppe Nuti et al., 2011.

techniques to scan news or tweets on Twitter to forecast future price movement or volatility. The pre-trade analysis includes three mathematical models which are:

1. The alpha model which predicts the financial instruments future behavior to trade.
2. The risk model which evaluates risk levels associated with the financial instruments.
3. The transaction cost model which calculates the potential costs associated with trading the financial instruments.

The trading signal generation creates signals to traders by applying technical analysis to price charts. Trading signal generation consists of the portfolio construction model which decides what portfolio of financial instruments should be owned going forward and in what quantities. The input to this model is the results obtained from the alpha model, risk model and transaction cost model. The trade execution model executes the trades and place orders in one or more exchanges, making several decisions with constraints on trading costs and trading duration.

Mobile Internet Market

(Andreas Kaplan, 2012) Defines mobile marketing as “any marketing activity conducted through a ubiquitous network to which consumers are constantly connected using a personal mobile device”. Mobile marketing is a cheaper, very effective and fast growing method to promote products and services to consumers (Ververidis & Polyzos, 2002). Based on the location of a mobile user which can be obtained using radio-frequency identification (RFID) tags, Bluetooth or GPS information advertisements can be sent to the mobile in real time based on his/her proximity from a store (Li & Du, 2012). In other words, companies with a strong mobile marketing presence and have an optimized website on the Internet will attract more visitors and more likely these visitors will be potential buyers of services or products.

Decentralized Autonomous Corporations

DAO organizations are decentralized organizations that can make decisions without people engagement by using smart contracts. Intelligent

techniques use these rules and protocols to help reduce transaction costs associated with actual legal contracts while providing security using cryptographic authentication to facilitate negotiation and enforces contracts performance.

Cryptocurrency

Cryptocoins are they only means to deal with DAO corporations. No central authority or banks can control cryptocurrencies systems. Bitcoins network is considered the first decentralized digital cryptocurrency system. It is a peer-to-peer (P2P) digital money system where the unit of currency is bitcoin. Electronic payments are implemented by generating transactions which transfer bitcoins directly between participants. Each participant transfers the bitcoin to the next participant by digitally signing a hash of the previous transaction and the public key of the next participant and adding these to the end of the coin. A payee can verify the signatures to verify the chain of ownership. A Proof-of-Work (PoW) system prevents people from double spending the bitcoins and verifies transactions without a central organization. Digital signatures corresponding to sending addresses are used to authenticate transactions, identify users' identities and control creation of new bitcoins. All bitcoin transactions are added to a unique public ledger called block chain. A block chain provides participants with a distributed trustworthy storage and contains every transaction done on the bitcoins P2P network and shared by all participants of this network. Each participant can own a copy of this block chain thus allowing him to monitor any other participant which prevents attacker from falsifying transactions or account balances (Satoshi Nakamoto,2008).

Smart Contracts

Small programs that replace legalese with computer programs that contain pre-written rules and logic in the form of "IF... THEN" statements and behave exactly as expected. Smart contracts

contain digital signatures and time stamps that prevent any potential contention between parties. When two parties digitally signed and deployed a smart contract on the network no unilateral party can cancel this transaction.

Internet of Things (IoT)

This technology forms a worldwide network for e-commerce where all digital devices, objects and human beings are interconnected to share information which reflects objects manufacturers, transportation and consumption and other details of people's life (Li H,2013). IoT opens a new exciting era in the areas of marketing and advertising. It provides companies and organizations with a powerful tool for marketing their products where marketers and advertisers have the opportunity to analyze customers' behaviors and respond to the needs of their audience with appropriate messages at the appropriate time on the appropriate devices. Figure 4 shows the architecture of an IoT e-business model which applies the concept of decentralized autonomous organizations (DAO). It is composed of four modules namely: entities and commodities which are considered the infrastructure of the IoT e-business model and the basic operating mode and transactions mode (Yu Zhang, 2016).

1. **Entities:** IoT integrates an extremely large number of heterogeneous entities such as DAOs, hardware entities and software entities that intended to improve efficiency and bring interconnectivity to all aspects of modern economy. Hardware entities include sensing devices or actuating devices. Software entities include applications that use sensed data, software agents that are responsible for entity's conceptualization and functionality or services. Software entities can search or purchase IoT commodities according to certain conditions.
2. **Commodities:** They are smart properties that can be traded or loaned via block chain using smart contracts. Smart properties in-

clude physical properties such as cars and houses and non-physical properties such as loans. Their ownership is controlled via block chain and smart contracts.

3. **Transaction Mode:** Bitcoin is adopted as the unit currency and IoTcoin as commodity exchange certificates and compatible with bitcoin. With IoT coin and smart contracts users can exchange the paid data or smart property or make deals with other users on the P2P without the involvement of a third party.
4. **Operation Mode:** The design and signing of the smart contract is accomplished in this stage. When a smart contract is executed Bitcoins and IoT commodities transfers are performed according to the signed smart contract (Yu Zhang, 2016).

Social Media

Facebook and Twitter are popular social media having great impact on the growth of E-commerce market which encourages strategic developers to consider social media in their strategic plans. Key information such as age, geographic location, language, popular phrases, keywords, behaviors, opinions and interests of users can be obtained from social media. Engagement with these users and delivering a needed support to them can influence their perception on a particular product. Based on a study involved 6000 social media users conducted in April 2013, 40% of the users bought their commodities after sharing them on social media websites, 71% are ready to buy products based on the feedback coming from social media while 74% depend on social media to make their

Figure 4. The architecture of IoT e-business
As adapted from Yu Zhang, 2016.

decisions. It was also found that Facebook influences 30.8% of social media users purchasing habits, while LinkedIn and YouTube influence 27% of social media site users respectively (Seave, 2013). These statistical results have encouraged E-commerce enterprises to rely on social media to gain competitive advantage and business values, influence customers perception, increase customer loyalty, satisfaction and retention, most importantly create brand awareness and build reputation then finally improve sales and revenues (Hea et al., 2013) (Melville et al., 2009).

Big Data Analytics

With the ever growing business data, E-commerce enterprises are now considering their data as big assets. Big data has the three characteristics which are volume, velocity and variety (3V's). Volume refers to the size of data in Terabytes, Exabytes or Petabytes while velocity refers to the speed with which data is captured and finally variety refers to the heterogeneous nature of data i.e. structured and unstructured datasets (Uyoyo Zino Edosio, 2014). Big data analytics hold many promises for providing business insights, analyzing consumer behavior as they can have deep insight into customers' needs, predict customers' behaviors, and for adapting of advertisements to fit consumers' different tastes. It can provide a suitable metric to measure the effectiveness in meeting customers' needs. Social media data is considered big data as it holds the 3Vs characteristics of big data. Text mining and semantic analysis are the two common techniques to analyze social media data (Tan et al., 2013). Predictive analysis is another big data tool that is used to identify patterns and learn from historical data to allow E-commerce vendors to predict customers' behavior and build an effective future marketing campaign (Shmueli & Koppius, 2011). Predictive analysis is also used by recommender systems to predict the preference or the rating of a customer towards a specific product while price management strategies use predictive analysis to set future prices.

Cloud Computing

Cloud computing has a significant effect on the performance of intelligent E-commerce models as it provides scalable and flexible services to the E-commerce enterprises on demand. It enables them to perform their computation task on the public cloud using pay-as-you-go style rather than purchasing hardware and software items. Pay-as-you-go pricing scheme is very flexible as it helps enterprises to pay for their consumed resources only, eliminate the costs for hardware and software maintenance, costs of upgrading and the wages for IT personnel. All these help E-commerce enterprises to decrease the cost of system building and maintenance and to maximize the utilization of their resources to get the maximum return on their investment (Danping Wang, 2013). E-commerce enterprises hosting their applications and data on cloud data centers enjoy both high availability i.e. 24x7 and reliability. In addition, cloud computing providers guarantee the scalability of applications running on their servers thus giving the clients the opportunity to scale up or scale down their computing resources if this is needed. Scalability supports e-commerce enterprises to continue offering their services to their clients even if there is sudden growing of demand. Another important advantage provided by cloud computing is storage replication where data is stored in multiple geographic locations to protect it from natural disasters. The huge storage capabilities of the cloud data centers are used to store the explosive growing customers' data which will become a growing problem if these enterprises are using local servers.

INTELLIGENT AND MODERN MODELS

Issues, Controversies, Problems

One of the major problems on the Internet is lack of advising where no human advisors are available to

advice customers online to identify what products better fit their preferences. Some researchers argue that using AI in e-commerce would result in a market being overtaken by machines. Also, there is a belief that decisions taken by human intelligence is much better than decisions taken by artificial intelligence techniques. However, some researches argue that artificial intelligence could be helpful to guide people in taking their right decisions but not replacing the human intelligence. As modern life becomes more complex people have no time to perform business in traditional ways which requires more flexible tools to facilitate people's life in doing e-business. Researchers argue that although modern tools have significantly flourished e-business but issues of adaptation, privacy and security are of main concern.

SOLUTIONS AND RECOMMENDATIONS

The major advantage of using artificial intelligent techniques in e-commerce business models is advising the customers on the items they want to buy through the Internet. Advising on the internet is important because there are no real persons to advice customers on the internet. This advice helps online customers to browse a large number of products (Prasad, 2003).

1. **Personalized Brokering Agents:** A personalized product-brokering agent is one of the B2C intelligent applications that depend on evolutionary agents to build an efficient agent-based ontology through collaboration and exchange of information with other product-brokering agents. Evolutionary agents in personalized product-brokering application use genetic algorithms and evaluation function to track user's preferences for a specific product. A user profile is required for the product-brokering agent to work efficiently. At the beginning a new product-brokering agent does not have enough information on

the products to recommend any of them to the user. Some keywords about products' features are required for product-brokering agents to start searching for products. To collect this initial information the product-brokering agent relies on other sources such as web crawlers called InfoSpider in (G. Pant, 2002). As an example, in the Handy product-brokering intelligent application an initial population of brokering-agents are created and evolved using genetic algorithms (Steven Guan, 2002). Each agent has a unique name to differentiate it from other agents. Newly created brokering agents acquire their prior knowledge about products using the Internet. Figure 5 shows an evolutionary intelligent agents system.

2. **E-Auctions:** Excellent e-business tool to help B2C, B2B and C2C manage complex and challenge negotiation in real time. E-auctions take place in e-markets where sellers present their goods on the auction website and bidders submit their bids for the product within a certain period. E-auctions allow sellers from any region in the world to offer their bids to the buyer. E-auctions significantly reduce the time required for sending material, product specifications from the buyers, negotiating with the sellers and finally receive quotations. Two main types of e-auctions are available: forward e-auctions and reverse e-auctions. In forward e-auctions, several buyers offer their bids to a seller see Figure 6. The goal of forward e-auction is to push the price upwards to get the highest offered price. In reverse e-auctions, a single buyer let potential sellers to know about his/her intention to buy items they sell through sending emails or making posts on social media see Figure 7. The goal of reverse e-auction is to push the price downwards to get the lowest price to pay.
3. **Recommender Systems:** An e-business tool to predict user responses to items.

Figure 5. Evolutionary intelligent agents system
As adapted from Sheng-Wei Guan et al, 2005.

Recommender systems are either based on the CBR or ACF technology. Items recommended to users by CBR recommender systems are based on the properties of these items where similarity of items is determined by measuring the similarity in their properties. Items recommended to the users by ACF recommender systems are those items preferred by similar users. The two main entities in recommender systems are:

- Users,
- Items.

The relationship between users and entities is a preference relationship where users have preferences for certain items. By using the users' feedback on products the recommender system

Figure 6. Forward auction

Figure 7. Reverse auction

can adapt automatically and its performance is enhanced comprehensively (Weihong and Yi, 2006). A utility sparse matrix represents the degree of preference of a certain user and to a specific item. Degrees of preferences come from an ordered set of integers for example integers from 1 to 5. Figure 8 shows $M \times N$ utility matrix where M the number of users, N the number of items and d_{ij} is the degree by which user i prefers item j .

Since the utility matrix is sparse, meaning that most of its entries are unknown, the recommender system is required to predict the values for these entries.

4. **E-Procurement:** An e-business tool that facilitates the stages of the procurement process: searching, sourcing, and negotiation with suppliers, ordering, receipt, and post-purchase review (Croom & Brandon-Jones, 2004). E-procurement allows organizations to cut their costs, control budgets, adds transparency to their spending, auditing and approvals. There are three types of e-procurement systems: buyer e-Procurement systems, seller E-procurement systems and online intermediaries (Koorn, Smith and Mueller, 2001).
5. **E-Payment:** Facilitates transfer of money between suppliers and vendors through the Internet. Figure 9 shows a secured e-payment system where data is transmitted on a secured communication channels. Types of e-payments include:
 - a. **Cards:** These include credit cards, debit cards and prepaid cards.

- b. **Online Payments:** Where a customer pays for a product or a service through the Internet.
 - c. **Mobile Payments:** Payments can be made by either sending SMS messages, transmit a PIN number or use WAP to make online payments.
 - d. **Automatic Teller Machines (ATM):** These are fixed stations equipped with communication channels, keyboards, screen monitors to allow clients to make transactions or access information.
 - e. **P2P Payments:** Which allow a person to pay another person using account or prepaid card. A good example for this mechanism is PayPal that was recently purchased by Ebay.
6. **Amazon EC2 (Elastic Compute Cloud):** A Web-based service with practically unlimited number of virtual machines. EC2 allows business subscribers to execute their applications in the Amazon.com computing environment. New York Times and Eli Lilly & Co. have benefitted from using EC2. The former transformed its TIF data to PDF data with a cost of 3000 USD while the second decreased the cost of data analysis to 89 USD which usually spent one million USD before (Danping Wang, 2013). Figure 10 shows the cloud computing E-commerce industry chain. With this structure the E-commerce enterprise will be directly served by the cloud service provider rather than the IT firms group as in traditional E-commerce industry chain.

Figure 8. The utility matrix M users with N items

	Item 1	Item 2	Item 3	Item 4		Item N
User 1	d_{11}	d_{12}	d_{13}	d_{14}		d_{1N}
User 2	d_{21}	d_{22}	d_{23}	d_{24}		d_{2N}
User 3	d_{31}	d_{32}	d_{33}	d_{34}		d_{3N}
User 4	d_{41}	d_{42}	d_{43}	d_{44}		d_{4N}
.....						
User M	d_{M1}	d_{M2}	d_{M3}	d_{M4}		d_{MN}

FUTURE RESEARCH DIRECTIONS

Internet of Things (IoT), cloud computing, big data analytics, social media and mobile apps are the tools going to shape e-commerce in the future. IoT e-business models and their applications in e-business is a promising area of research. New mobile search apps are developing very rapidly and consequently mobile search on the Internet is expanding very fast but the real challenge is how to adapt e-business strategies and models to the mobile environment. Converting unstructured data captured from social media such as tweets and videos to make meaningful insights that benefit E-commerce enterprises is a big challenge. Cloud computing will be the future platform for all real time applications and thus adapting e-business models to the cloud computing environment will be very promising for e-commerce enterprises seeking high availability, reliability and scalability for their online services. Users' privacy protection especially in the public cloud is still an important area of research. Protection of personal information and online transactions of customers will help E-commerce to grow and flourish.

CONCLUSION

In this chapter, the most common intelligent techniques applied in e-commerce models such as intelligent agents, CBR techniques and collaborative filtering technique have been discussed. Their implementation in the most common E-commerce models namely e-brokers, e-auctions, e-procurements, e-payments and recommender systems have been presented. With the advances in communications technology, smart phones technology and distributed computing algorithms new modern tools have been introduced to flourish E-commerce models. Modern tools which include algorithmic trading algorithms, social media, mobile marketing, big data analytics and cloud computing have been presented. Their influences on e-commerce models have also been discussed.

KEY TERMS AND DEFINITIONS

Big Data: A type of structured and unstructured data that is characterized by its big volume usually measured in Terabytes, Exabytes or Petabytes and requires specific hardware and software tools for processing.

Cloud Computing: A real-time distributed computing environment where data and applications are stored on globally distributed data centers which guarantee flexibility, availability, scalability, high storage capabilities and data replication.

E-Commerce: Doing traditional business over the Internet.

Intelligent Techniques: Artificial intelligence techniques that allow computers to perform complex tasks just like humans can do such as: understanding words meaning, decisions making and controlling complex objects.

Internet of Things: The ever growing network of heterogeneous objects such as digital devices, software objects and human beings interconnecting to interact and exchange information.

Mobile Marketing: Broadly engaging with customers through advertisements, messages and apps on mobile devices.

Social Media: Websites and online applications that allow large group of people to communicate, socially interact, exchange information and share opinions.

Online Mediation in E-Commerce Matters

Ángela Coello Pulido
University of Vigo, Spain

INTRODUCTION

Conflict is not an exceptional fact in human being's life but an ordinary phenomenon in relationships between parties who have different points of view and different positions. Society cannot be based in a permanent conflict situation. Therefore, legal systems have standardized some mechanisms which have been designed to solve different sort of disputes between or among individuals or organizations or between or among the firsts and seconds. Some of these systems are hetero-compositives (trial, arbitration) and some of them are auto-compositives (mediation, conciliation, negotiation, etc.).

Mediation is one of the auto-compositives mechanisms created to resolve differences between disputants and it is included in the so-called Alternative Dispute Resolution (ADR), that is to say, it allows an out-of-court solution. This system, which is getting more and more significant, consist of a way in which the parties negotiate by themselves to get an agreement with the help of a third, the mediator, who is impartial and neutral. In mediation table the parties defend their own positions and the mediator tries to emerge the true interests of the parties as only with the base of the interests, the amicable settlement will be possible and effective. As Fisher, Ury and Patton (2012) have pointed in their *Getting to yes. Negotiating an agreement without giving in*, "for a wise solution reconcile interests, not positions" (p. 42).

An important issue should be taken into account: in this way of problem solving, one of the negotiators could be more influential or more powerful than the others. Therefore, the mediator should assume the role of a professional who is

called to balance the leverage between or among negotiators. This is one of the biggest advantages of mediation with regard to traditional negotiation.

Alternative Dispute Resolution (ADR), in general, and mediation, in particular, have been gradually evolving through years to be adapted to the new times. Thus, they became into Online Dispute Resolution (ODR) and online mediation. Online mediation is one of the Online Dispute Resolution (ODR), that is, one of the Alternative Dispute Resolution (ADR) which uses Information and Communications Technology (ICT) as a key element in resolving process. The emergence of ADR as legal resources to problem solving and their effectiveness, motivate to use them when circumstances allow it. Mediation, which is having more and more acceptance, can be carried out by using electronic instruments without losing its essence.

One of the fields where online mediation could display all its charm is e-commerce. E-commerce has some virtues that transform it in a very useful way for market. It uses the Internet to do business. World Wide Web and mobile apps became the protagonist of this new reality. Consequently, consumers and users more easily access the market while companies improve their business.

E-commerce has increased its importance in the last years because of its usefulness in business world. Information and Communications Technology (ICT) is an unquestionable reality and, because of that, online relationships should be developed in an agile, certain and peaceful way. Consequently, obviously it should be considered that if e-commerce allows the development of online relationships, conflicts arising from these relationships also must be resolved online. The

reason is that it would not be logical to approve the e-commerce relational virtues and break them from the moment the conflict arise.

In short, it is clear that online mediation has some important advantages (lower-cost, faster, etc.). However, on the other hand, despite the virtues of online mediation, it could also reveal some disadvantages (difficulties in the use of ICT by some citizen, Internet connection problems, etc.). Therefore, these risks should be taken into account.

The aim of this chapter is to describe why online mediation is an appropriate instrument for conflict solving in e-commerce field and what are some of the advantages and disadvantages of this ODR not only for citizens but also for organizations.

BACKGROUND

The early moments of e-commerce could be found in the late years of 20th century but it was in 21th century when this kind of trade became into a revolution thanks to the improvement of technology and telecommunications. ICT and our social system are closely connected, which makes it impossible to understand one without the other (Garriga Domínguez, 2012, 67).

However, cyberspace is not always a peaceful space. Where information and communication operate in a high, fast and agile level and where contracts can be concluded at the click of a mouse, frequently appear the misunderstandings, the interest clashes and, definitely, the differences between and among the e-commerce users. Misunderstandings, delays, mistakes, late payment and non-payment are some of the conflicts that can arise in e-commerce transactions.

Conflicts are often solved in a judicial process. However, when it is possible, an amicable settlement could be the best option in order to get an effective solution. Especially in the complex area of ICT. Thus, online mediation was born as a system that is adapted to the new times.

In such a context, it could be considered that face-to-face mediation could be more appropriate due to possible communication difficulties and possible problems in information exchanges in online option. Traditional mediation is very virtuous because of the personal meetings. This personal interaction allows the mediator to guide conversations and to build an environment for good communication trying to moderate discussions and helping the parties to approximate their interests. However, the task could be more difficult in online mediation because the absence of personal meeting that could work as a barrier for a good communication. On the contrary, some have thought that online mediation has useful virtues. For instance, it has been argued that online mediation has more similarities than differences with respect to face-to-face mediation (Alzate Sáez de Heredia, 2008, p. 8). It could be very useful when the parties are separated geographically or, even, when communication between them is especially difficult. Furthermore, it has been said that as well as cyberspace provides an environment to observe new sources and patterns of conflict, technology provides the opportunity to consider new approaches to conflict resolution (Katsh, 2001, p. 812).

In opinion of Cortés (2011), “there are some misconceptions about ODR, such as the idea that ODR is only valid for small claims, or that ODR exclusively relies on automated technology, or that ODR can only deal with online disputes” (p. 2).

In any case, the reality is that online mediation is working properly. To that effect, it could be developed by different instruments such as e-mail, video conference or even a virtual platform that the mediator uses to that task; definitely, resources for reproducing sound, images and texts. In fact, written exchanges are not strange in online mediation. If the mediator decides to use a special platform, this instrument should be used not only for video conference but also for upload and download data and documents. Besides, it should have a schedule for mediation program-

ming, a notifications system, instant messaging, text message and a documentation management system. All of this in a confidential environment.

ONLINE MEDIATION IN E-COMMERCE. ITS USEFULNESS

E-commerce provides a number of features that reveal its success and effectiveness. Some of them are its ubiquity, its speed or its ease. Firstly, the ubiquity of e-commerce refers the opportunity of puts somebody in touch with another person who is at great distance from them and at any time. Instead of a physical marketplace, the result is a marketplace, that is to say, a marketplace which is extended beyond traditional boundaries and removed from a temporal and geographic location (Laudon & Traver, 2015, p. 52). Secondly, the speed is a consequence of ubiquity because if e-commerce operates at any place and at any time, many obstacles can be overcome and it can obtain the speed as a result. Lastly, the ease of e-commerce is evidenced by the fact that at the click of a mouse, the transaction can be formalized.

Therefore, e-commerce operates from a global perspective. Thus, it is reasonable to believe that conflicts which emerge in this scenario should be solved by an instrument that has the same useful features. It would not be logical to consider such a useful marketplace if it did not exist an available mechanism with similar advantages for problem solving in this context.

Online mediation allows maintaining important advantages of the e-commerce. Its link with the ICT makes it a perfect candidate for that task. Online mediation shares the ubiquity, speed and ease. Online mediation can work at any place if connection is possible. Besides it is speedy because it avoids the obstacle of geographic distance between the parties and mediator and easy for use to the extent that people is able to use electronic mechanisms correctly.

There is one important idea that should be taken into account in any study of the ODR which is the consideration of technology as a Fourth Party.

This idea was first proposed by Kasth & Rifkin in their *Online Dispute Resolution: Resolving Conflicts in Cyberspace* (Kath & Rifkin, 2001).

Relating to mediation, on the one hand, traditional mediation has, at least, the following three participants: the mediator and two parties in conflict. On the other hand, online mediation has, at least, the following four: the mediator, the two parties in conflict and the ICT which include additional advantages to this auto-compositive ADR.

However, something should be considered: despite the unquestionable advantages of online mediation, it can also have some disadvantages because of its newness. In other words, due to ICT are relatively new technologies, online mediation has a shorter history than traditional mediation. The lack of a high experience brings to light certain difficulties that should be noticed and that can be overcome at the same time that technological progress.

Both advantages and disadvantages will be analyzed in the following.

Advantages of Online Mediation in E-Commerce

Understanding of advantages of online mediation requires the difference between two types: the advantages which come from the use of certain technology and those that result from the inexistence of a face-to-face meeting as in traditional mediation.

Firstly, resulting from the intervention of ICT, the online mediation shares some characteristics with the e-commerce. Therefore, it is very useful in this field.

Before anything, online mediation is useful because of its ubiquity. The ubiquity means the possibility of maintain that contact between parties in conflict without connecting simultaneously but at different times. On the one hand, the global reach allows people located in different geographic points to solve their problems, emerged during e-commerce transactions, avoiding additional costs as trips for instance. On the other hand, the asynchronicity manifestations are found in the

possibility to establish direct contacts at different times depending on the Internet connection of the parties and this has a special importance relating to the time zone if the parties are at a great distance. For instance, this feature of online mediation is useful if the conflict emerges between a consumer and a trader who is established in a different State with a different time zone.

When mediation is carried out through the use of video conference, communication is established at the same time. This would be an appropriate option if the parties are in the same time zone and have the same time availability. However, it could be developed by other ways like e-mail or chat. In the second case, parties can connect depending on their availability.

Moreover, given that online mediation allows the parties to solve their differences whenever and wherever they are, the process is speedy because of it is able to make the most of time, in other words, it is able to optimizing time.

In addition, mediation practiced online tries to be easy by using ICT. These new technologies can facilitate operations. Simple things like documents sharing or record the minutes. But also more complicated matters like permitting the ubiquity that has been mentioned above.

Secondly, beyond the technical issues, online mediation is very useful, for example, in order to avoid the difficulties of a face-to-face meeting. Sometimes people are not able to face a problem solving process in front of their adversary, but they get good results in front of a computer screen.

Disadvantages of Online Mediation in E-Commerce

Just like the advantages, understanding of disadvantages of online mediation requires the difference between two types: the disadvantages which come from the use and access to certain technology and those that result from the inexistence of a face-to-face meeting as in traditional mediation.

The new Information and Communications Technologies are becoming more and more im-

portant and useful. However, some doubts (or disadvantages) exist on these technologies, which are reflected in the online mediation.

One of these disadvantages, which is very important, is the doubt in relation to the secure information exchange. The mediation process needs an information exchange and this requirement could result in the parties' mistrust because of the possibility of digital recording of these details and their retention.

In these circumstances, this issue can result in two problems. On the one hand, the concern of the parties to disclose relevant information. Each of these participants has some data and could think that an online process could result in a loss of control. Consequently, online mediation entails the risk of concealing information that could lead to an effective agreement.

On the other hand, appears the right to privacy. Computers can store a significant amount of information. Automatic processing of personal data has led to the birth of a new human right: the right to informational self-determination which is included in the Third Generation of human rights. Information is power in our society and this power is decisive when computing transforms partial and disperse information into mass and organized information; therefore legal framework of computing has priority interest (Pérez Luño, 2006, p. 32).

Difficulties linked with information are serious because information plays a significant part in any negotiation, including mediation. Information managed at the preparatory stage and its use during the rest of the process could be one of the essential elements of negotiation.

Another disadvantage that could be arise from online mediation with respect to traditional mediation is a possible poor understanding of the correct use of ICT or, even, an almost ignorance (not a complete lack of knowledge about the existence of these technologies because e-commerce requires a minimum). Perhaps, one or more of the parties do not have enough skills or expertise in the use of ICT. Maybe they are not used to

using these technologies. And not just this, but also it is possible a situation of lack of access to these technologies whenever the user wants. Information and Communications Technologies are relatively young. Therefore, not everyone has knowledge about how to use it correctly as well as not everyone accesses it at any time. It is necessary a technological equality (Vilalta Nicuesa, 2013, p. 292).

The lack of skills or expertise or the access difficulties could result in a imbalance between the parties. Maybe some of them are not communicating properly and this makes difficult their participation in mediation or more difficult than the other parties' participation.

There is an important difficulty in online mediation which is the necessity of global standards, that is to say, common rules to every problem solving process. It must be kept in mind that the ubiquity of this method allows the start of both national and international mediation processes. Thus, cross-border processes require the determination of applicable law. Therefore, it could be useful the implementation of common standards for every problems solving process in this field.

Finally, besides, exist other problems in this field that are more general: computer virus, software errors, computer malfunctions, etc.

Secondly, should also refer to disadvantages of online mediation which come from the inexistence of a face-to-face meeting as usually happen in traditional mediation. For instance, this method result impersonal and it is specially the personal meeting one of the greatest virtues of mediation.

SOLUTIONS AND RECOMMENDATIONS

In view of the foregoing, it should be noted that both advantages and disadvantages of online mediation have to do with the access and use of Information and Communications Technology, not with mediation features themselves.

Therefore, on the basis that online mediation has certain advantages as an auto-compositive system created for problem solving, just in the same way of traditional mediation, the problems or disadvantages should be manage properly. Thus, parties should take care of their reserved information, privacy, etc., becoming aware of the real process they are facing.

ICT are very useful in mediation, especially in a field like e-commerce. However, it is recommended to analyze each particular situation at the very beginning of mediation in order to make the decision of going through an online way or a traditional way. Besides, if the circumstances demand it, it is advisable that the parties put an end to online mediation to begin a traditional one.

In addition, it might be considered that the ICT future development could correct some of the disadvantages of online mediation. For instance, solving difficulties as those related to the right to privacy. But others will stay because they are a consubstantial part of the mediation. For example, the difficulties in information exchange.

FUTURE RESEARCH DIRECTIONS

Access to information, global communication, speed transactions, etc. These are some of the things that technology allows to consumers and users, service providers, traders and general public. As ICT, e-commerce is becoming more and more usual, successful and, ultimately, useful. ODR operate in this field with the same benefits.

Consequently, to the extent that ICT develops, also ODR are gaining popularity. According to Rule (2015), "technology is changing not only the way we communicate; it is altering the way we disagree and the way we resolve our disputes" (p. 5).

As a result of the foregoing, it seems that future research will continue in two ways: the technological study and the legal-social study. Besides, the legal-social study will depend on the technological study because of the need for the

regulation of the relationships in the new context of cyberspace to respond to changes as they arise.

Therefore, new communication channels can be implemented in order to improve ORD, in general, and online mediation, in particular, at the same time as a solution for an appropriate regulation is sought. In other words, and referring to e-commerce, this trade can be improved by technological advances and, in the same direction, online mediation will be adapted to the e-commerce users' needs.

But another line of research should be taken into account which is the evolution from ADR to ODR given that the unquestionable ICT emerge and development. ADR have proved their success and effectiveness. Now is time for ODR.

CONCLUSION

E-commerce is here and it has come to stay. This type of trade entail a new space for relationships development in ICT area; therefore it is necessary an effective mechanism for problem solving in this field. This system should be adapted to these technologies; as a consequence, online mediation is an appropriate method in order to face this task.

Online mediation has certain advantages with respect to traditional mediation, that is to say, mediation based on face-to-face meetings. However it has also a number of disadvantages or difficulties. Some of these advantages and disadvantages have emerged as a result of the use of ICT and others as a consequence of avoiding in-person processes. Nevertheless, the most important fact about the link between e-commerce and online mediation is the similar characteristics that they have and that transform online mediation in an appropriate mechanism for problem solving in the sphere of this trade: ubiquity, speed, ease.

In conclusion, if e-commerce has a variety of features that make it so useful and effective, the mechanism for problem solving in this field should have similar advantages. Online mediation has them. Such a useful mechanism as online mediation is part of contemporary advance. Digital Age is here.

KEY TERMS AND DEFINITIONS

Alternative Dispute Resolution (ADR): Systems created to get an out-of-court solution to differences between parties who have different points of view and different positions.

Amicable Settlement: A deal which comes from a consensual agreement of the parties in a negotiation process.

Auto-Composition: A way for problem solving which is based in an arrangement emerged from the free will of the opponents.

E-Commerce: The use of the Internet for doing business between and among individuals or organizations or between or among the firsts and seconds.

Information and Communications Technology (ICT): Technologies which have been created to manage and transmit information.

Online Dispute Resolution (ODR): Systems created to get an out-of-court solution to differences between parties who have different points of view and different positions by using Information and Communications Technology (ICT) as a key element in resolving process.

Online Mediation: An Online Dispute Resolution which consists of a way in which the parties negotiate by themselves to get an agreement with the help of a third, the mediator, who is impartial and neutral.

Reputational Mechanism in Consumer-to-Consumer Online Commerce

E**Mikhail I. Melnik***Kennesaw State University, USA*

INTRODUCTION

The emergence of the Internet is, in many ways, an historically similar event to the industrial revolution; it has fundamentally changed the cost of transmitting, presenting, and processing information. However, the new means of transmitting and presenting information do not insure its quality. Early in the Internet development, asymmetry of information presented a significant challenge to the adaptation of the Internet in consumer-to-consumer commerce. However, with the help of simple, intuitive, and transparent instruments such as customer review or rating mechanisms, consumer-to-consumer online commerce has been able to overcome this potentially serious obstacle and flourish, changing the way consumers shop.

BACKGROUND

Asymmetry of Information

Asymmetry of information occurs when the parties involved in a transaction have different access to the relevant for the transaction information. The issue of asymmetry of information has been studied by economists for many decades. In 2001, George Akerlof shared the Nobel Prize in economics with Michael Spence and Joseph Stiglitz for their monumental work in the area of asymmetry of information in economics. His groundbreaking work formulated the problem on the example of used car sales, Akerlof (1970). When selling a used car, the seller knows far more about the car than a perspective buyer, putting the buyer into

a position of disadvantage. The asymmetrically distributed information not only puts the party with less information at a disadvantage but also creates a disincentive for that party to participate in the transaction. This latter characteristic can threaten the growth and development of an impacted market.

In online consumer-to-consumer commerce, the issue is magnified by the fact that there are two channels for the emergence of asymmetry of information. First, in most cases, the perspective purchasers may not have any direct way of examining the goods they intend to acquire online. Second, historically, buyers have been required to submit payments prior to the seller delivering the item. This dynamic implies that the buyer has to rely on the seller for the accuracy of the item's description and compliance with the terms of transaction.

The success of online consumer-to-consumer marketplaces, including one of the largest such platforms – eBay, serves as an excellent and innovative example of addressing the problem of asymmetry of information. Typically, a consumer-to-consumer website merely serves as the platform for its users to sell/purchase various goods and services. This limited role places the burden of compliance with the terms of transaction on the individual participants and therefore presents the possibility of asymmetry of information.

eBay Rating Mechanism

eBay is perhaps the largest and most recognized consumer-to-consumer website today. eBay is set up as a platform for third party users to sell

DOI: 10.4018/978-1-5225-2255-3.ch247

their goods. eBay corporation merely serves as the marketplace and brokers the trades, but the actual compliance with the terms of transaction is left up to the individual users. By this setup, eBay exposes its users to potentially serious asymmetry of information issues, including the accuracy of item description and compliance with the terms of transaction, such as shipping the product, selecting the correct shipping option, shipping it in a timely fashion, etc. The problem is further highlighted by the customary requirement that the buyer submits the payment prior to the seller shipping the item. Despite the obvious nature of the problem, eBay has become a flourishing consumer-to-consumer platform with the quarterly gross merchandise trade approaching nearly 22 billion dollars in the fourth quarter of 2015 (eBay, 2016).

eBay was able to overcome the asymmetry of information problem by creating a simple and intuitive user rating mechanism. In February of 1996, just six months after the launch of the website, eBay introduced its rating system, back then, referred to as feedback (eBay, 1996). After completing a transaction on eBay, each party can rate the performance of the other along three choices: positive, neutral, and negative. eBay converts these individual responses into a continuous variable, the eBay rating, which is simply the difference between the number of positive and negative responses. This rating is then displayed next to the user's id. In the case of sellers, it is easily visible on every listing they place on eBay.

The eBay rating of a user only captures responses left by those users with whom the user had transactional experience on eBay. This reduces the ability of manipulating someone's rating. Furthermore, although eBay users can rate each other after every transaction, the rating only measures responses left by unique users. This implies that if two users participate in multiple transactions between themselves and place multiple positive responses about each other, these multiple responses will count as one, because they are left by the same user. This characteristic of the eBay rating mechanism further enhances the ability to resist manipulation.

Over time, the rating mechanism underwent some changes. Today, each seller's auction not only displays the overall value of the seller's rating, but it also reports the percentage of positive responses. In addition, buyers have the ability to rate sellers on various individual aspects of transaction experience. These may include the accuracy of item description, the quality of communications, expedience of shipping, and shipping and handling charges.

The simplicity of the mechanism not only makes the process of evaluating someone's performance on eBay easy, but it also makes the interpretation of the rating mechanism rather straightforward. This is particularly important for sellers. For buyers, the rating is arguably less important (Melnik and Alm, 2002). The seller's overall rating conveys the information about the net number of praises left by other unique users who had transaction experience with this seller. Thus, the rating can serve as a signal of reputation, and thereby help address the problem of asymmetry of information and promote trust (Resnick and Zeckhauser, 2002).

Other online consumer-to-consumer platforms have developed their own, similar to eBay rating mechanisms. One example is Yahoo Auctions. During 1998 – 2007, Yahoo competed with eBay in the auction space (in the U.S. market) and employed a rating mechanisms that was similarly constructed (Melnik, 2011).

SOLUTIONS AND RECOMMENDATIONS

Empirical Evidence

A rising price (English design) auction outcome can be analyzed as a two-step process. First, an auction may or may not result in a sale. Second, if an auction results in a sale, then its price is determined by the willingness to pay of the bidder with the second highest willingness to pay (assuming there are more than one bid). This

two stage nature allows for the empirical analysis of the effect of the seller's rating to progress along several venues: estimating the effect on the probability of sale, willingness to pay (including censored observations, i.e. observations with no bids), and willingness to pay for sold items only (including a more restricted approach where only observations with multiple bids are present).

Seller's Rating and Buyer's Willingness to Pay

One popular empirical approach has been to estimate the willingness to pay. Since willingness to pay is censored for those listings where no bids were received, i.e. the listings resulting in no sale, a censored regression technique, such as the Tobit maximum likelihood estimation method, became a popular approach. In an eBay auction, the seller has the choice of the starting or opening price. Since opening prices can vary from listing to listing, the proposed variation of the Tobit estimation technique by Amemiya (1984) has become frequently used in studies using eBay data. Amemiya (1984) modified the Tobit model to allow for variability in the censoring point across observations. The use of this variation of the Tobit model allows for grouping of all observations (censored, i.e. with no bids, and uncensored, i.e. with bids) into one dataset. For empirical illustrations of this approach see Dewally and Ederington (2006), Melnik and Alm (2002, 2005), and Reiley et al. (2007).

These studies generally find that the seller's reputation has an impact on the buyer's willingness to pay in online auctions. Dewally and Ederington (2006) use data on collectible comic books and show that a higher reputation increases willingness to pay. Furthermore, they demonstrate that the effect is larger for those items that are not professionally graded (i.e. items with third-party certified product characteristics). Melnik and Alm (2002) focus on a homogeneous product, a 5 dollar U.S. gold coin which derives virtually all of its value from its gold content. They demonstrate that the seller's overall rating has a positive effect on

willingness to pay and their negative reputation has a significant penalty (Melnik & Alm, 2002). Reiley et al. (2007) find that the overall reputation has no statistically significant effect, while the negative reputation significantly reduces the buyer's willingness to pay.

Probability of Sale

Another approach has been to investigate the probability of sale. Here, a simple probit or logit model is employed to investigate how the various characteristics of an auction, including the seller's rating, impact the probability of sale.

Using a logit model, Eaton (2002) demonstrated that negative feedback reduced the probability of sale. The results also showed that the seller's positive rating had no significant impact on the probability of sale (Eaton, 2002). Employing a probit model, Jin and Kato (2008) showed that the seller's positive reputation (feedback) increased the probability of sale while the negative reputation (feedback) decreased it.

Jin and Kato (2008) used collectible sports trading cards in their study and the results demonstrated that a certification by a third party reduced the effect of the seller's negative reputation. Their findings demonstrated that the presence of certification by a credible third party reduces the uncertainty about the item. This reduces the signaling property of the seller's rating, thereby reducing its importance in the buyer's decision.

Sold Items Only

A number of empirical studies focused on sold items only. This approach enables the researcher to directly estimate the willingness to pay of the second highest bidder using the OLS technique. However, the downside of this approach is that it ignores all observations with no bids (or in the case of the more restricted studies, one bid listings as well). It is important to note that in an English auction, the winning bid represents the willingness to pay of the bidder with the second

highest valuation. This implies that listings with a single bid become censored as the second highest valuation is unobserved and lies below the observed bid. As a result, some of the studies focused on successfully completed listings only restricted their data to observations with two or more bids. For example, Houser and Wooders (2006) restricted their estimation to observations with at least two bids and showed that the seller's positive rating increased the winning bid while the negative rating decreased it. Another illustration of an earlier work using sold only auctions was a study by McDonald and Slawson Jr. (2002). This study also found that a higher seller's rating resulted in a higher closing price and an increased number of bids.

Homogeneous vs. Heterogeneous

As previously noted, asymmetry of information presents two issues for perspective buyers in online consumer-to-consumer commerce: uncertainty about the accuracy of the product description and uncertainty about the seller's compliance with the terms of transaction.

One of the main challenges faced by anyone who wishes to conduct an empirical investigation using eBay generated data is the choice of the product for data collection. Some products might exhibit significant variability in item-specific characteristics, presenting challenges for empirical investigations. For example, in the market for used textbooks, some books might be more worn out than others. If one does not control for the quality of each individual textbook, one omits an important regressor.

This induced many researches to focus on items with controlled item-specific characteristics. Such controls can come in a variety of ways. For some products, the mere presence of a photo of the actual item may be sufficient. Although, a photo does convey a lot of information to the perspective bidders, such information is not easily quantifiable into a continuous numerical variable. As a consequence, a frequently favored approach

by empirical researchers was to focus on a product that had easily measurable item-specific characteristics, had a third party evaluation (certification), or was simply one that exhibited no heterogeneity.

Houser and Wooders (2006) selected Pentium processor chips in their study. Since Pentium processors are unlikely to exhibit significant item-specific variability (for each particular processor model), this practically ruled out heterogeneity. Many investigators decided to focus on items with easily measurable quality and third party certifications, e.g. collectible coins. Examples of such studies include Lucking-Reiley et al. (2007), Bajari and Hortacsu (2003), and Melnik and Alm (2002, 2005).

Another approach to address the issue of item-specific heterogeneity is to conduct a controlled experiment. This approach allows not only to control for the item-specific characteristics, but also for the behavior of the seller. One such study was done by Resnick et al. (2006) in which the same established eBay seller sold identical items using two different eBay accounts: their own established account and a new account with a zero rating (established for the purpose of the experiment). The results demonstrated that the difference in willingness to pay was about 8.1% of the selling price in favor of the account with the higher rating (Resnick et al., 2006). This study suggested a rather large penalty being placed on a new seller and highlighted the importance of the eBay rating for sellers. As discussed later, such penalties can play an important role because they increase the costs sellers face when switching to a competing platform, thereby potentially reducing the competitive pressure on the platform itself.

However, item-specific heterogeneity is a double-edged sword as it also presents a unique opportunity to differentiate between the various roles the reputational mechanism plays. In the case of a product with unobserved item-specific characteristics, the seller's reputation signals two important pieces of information: the reliability of the seller in complying with the transaction's terms, and the reliability of the seller in accurately

describing the item. In the case of a homogeneous good, the signaling role of the mechanism is reduced to the first of these properties only.

Melnik and Alm (2005) attempted to analyze these different signaling properties of the seller's reputation on eBay by contrasting uncertified, high quality (AU—almost uncirculated) collectible U.S. Morgan silver dollar coins with the same category coins that were certified by an independent coin grading agency. Their results indicated that the overall seller's rating played an important role in the case of the non-certified coins. However, in the case of the certified coins, the overall rating was insignificant while the negative rating had a statistically significant negative impact on the willingness to pay. It is important to note that the average prices differed sizably between these two groups of coins, with the certified coins being significantly more expensive on average (\$327 versus \$58). The results suggested that the negative rating conveyed the signal of the reliability of the seller when it came to complying with the terms of the transaction. This is because in the case of a more expensive item, the consequences to the buyer of the seller's failure to comply with the terms of the transaction were more severe.

eBay Seller's Rating as a Barrier to Entry

As the preceding discussion illustrates, the eBay rating mechanism has played an important role as a signal of information about the quality and reliability of the seller in an online auction. The rating mechanism enabled eBay to overcome the asymmetry of information problem in online commerce prior to the development of various forms of buyer protection. In this sense, the rating has played an important historical role in the growth and popularity of the eBay website (Brown and Morgan, 2006). However, the implications of the rating mechanism did not stop there.

The eBay rating mechanism has also created a sizable barrier to entry for competing to eBay consumer-to-consumer online platforms. Resnick

et al. (2006) demonstrated that the difference between an established seller and a newcomer can be around 8.1% of the sales price. Melnik and Alm (2002) show a much smaller but still sizable impact of the seller's reputation on the realized auction price. They find the difference in the willingness to pay to be about 4.8% between an established seller and a new one. These empirical findings indicate that an established eBay seller would potentially incur a sizable price penalty if they were to shift from eBay to a competing online auction platform and start there anew. Indeed, this characteristic of eBay rating was tested in the competition with Yahoo Auctions in the U.S. market.

FUTURE RESEARCH DIRECTIONS

Further empirical work is needed to draw more definitive conclusions on the exact effects of seller's reputation in consumer-to-consumer online commerce. This includes understanding the various signaling properties of online reputational mechanisms. As can be concluded from the preceding discussion, reputational mechanisms are also changing over time, presenting a further basis for empirical and theoretical research.

Emergence of third party payment mechanisms also alters the asymmetry of information in consumer-to-consumer online commerce. Credit cards, online payment mechanisms such as PayPal, all reduce some aspects of asymmetry of information, thereby altering the signaling properties of any reputational measures.

CONCLUSION

Empirical evidence of the impact reputational mechanisms have in online consumer-to-consumer commerce is less than fully conclusive. Although most studies have demonstrated that various aspects of the eBay seller rating mechanism have been shown to have statistically significant impact on the realized price and auction outcome, there

are other studies that show the impact to be statistically insignificant. However, several conclusions may be drawn from the empirical literature.

One such conclusion is that negative comments about a seller tend to matter more to the perspective buyers than positive comments. This is seen in both, the magnitude and statistical significance of the coefficients in most studies where the individual aspects of the seller's rating are used (Melnik and Alm, 2005). Another common observation is that the relationship between the seller's rating and the buyer's willingness to pay is non-linear and exhibits diminishing marginal returns. The first few positive comments may significantly matter to the potential buyers, but the marginal effect diminishes with rating. It can be argued that at some level, additional positive comments become insignificant. Finally, if the seller's rating indeed impacts the buyer's willingness to pay, then this rating may serve as a barrier to entry not only for other sellers, but for competing consumer-to-consumer platforms (see Melnik and Alm, 2005; Melnik, 2011).

KEY TERMS AND DEFINITIONS

Asymmetry of Information: Different parties have different access to the relevant information.

English Auction: A rising price auction.

Feedback: Comments posted online.

Online Reputational Mechanism: A structured presentation of feedback about a particular user of a website.

Opening Price: The starting price in an auction.

Reserve Price: The lowest acceptable bid to the seller, also the lowest binding bid.

Willingness to Pay: The maximum value the buyer is willing to pay for a given unit of a product.

Retail Prices and E-Commerce

E**Jihui Chen***Illinois State University, USA*

INTRODUCTION

In the pre-Internet era, consumers relied on media such as Sunday newspapers and flyers for product and price information. Such search process is time-consuming and unlikely to be exhaustive. The existence of incomplete information leads to price dispersion in the marketplace (Stigler, 1961). Recent advances in information technology have dramatically changed the manner in which consumers and businesses gather and transmit information.

Online shoppers enjoy enhanced search capability through effective tools. Search sites, such as Google and Yahoo!, become indispensable for comparison shopping. A recent comScore Media Matrix monthly qSearch™ analysis reports a total of 16.8 billion unique desktop search queries submitted in February 2016.¹ With the rising popularity of mobile devices, from smartphones to tablets, one would only expect a greater utilization of search engines.² Along with ever-increasing competition among online retailers, we would expect prices to converge in the new economy. However, an extensive literature on Internet prices has documented persistent price dispersion in various online markets. In this chapter, I review existing studies on the topic and discuss future research directions in light of recent developments with e-commerce.

BACKGROUND

The Internet provides an ideal setting for empirical studies with abundance of data.³ In this section, I review research on retailer prices on the Internet. In general, we may sort e-retailers into two categories:

web-based e-retailers (Dotcoms), such as eBay and Amazon, who exclusively conduct their business on the Internet and have no physical presence,⁴ and multi-channel retailers (MCR), such as Best Buy's online branch, which is an extension of the brick-and-mortar establishment.

Early studies usually compare online and offline prices on books, CDs, and DVDs sold in the U.S. (Bailey, 1998; Brynjolfsson & Smith, 2000) as these commodities were among the first available on the Internet. Gradually, the empirical literature expands to include a wide variety of products such as airfares (Clemons et al., 2002; Chen, 2006; Chellappa et al., 2011), automobiles (Zettelmeyer et al., 2006), pharmaceuticals (Stylianou et al., 2005), service supply products (Ghose & Yao, 2011), consumer electronics (Baye et al., 2004a, 2004b; Xing et al., 2004), groceries (Gan et al., 2007), and hotel rooms (Delos Santos et al., 2011), to name a few.

Recent studies also include international data. For example, Liu and Tang (2005) study the Chinese book market, Li et al. (2009) study the Australian DVD market, Mizuno et al. (2010) electronics in Japan, Koppius et al. (2004) Dutch flower auctions; Englmaier and Schmoller (2011) football game auctions at HATTRICK, U.K., Zhong and Ong (2011) prepaid phone cards at Taobao.com, China, and Richards et al. (2016) online groceries in U.K., to name a few.

The empirical literature often compares prices and price dispersion between online and brick-and-mortar sellers, and between Dotcoms and MCRs. While most have found lower online than offline prices and lower Dotcoms than MCR prices, there seems no general consensus regarding the level of dispersion across different distribution channels or types of e-retailers. However, it is clear that persistent price dispersion remains on the Internet.

DOI: 10.4018/978-1-5225-2255-3.ch248

Existing studies have developed several measures of price dispersion:⁵ In a given product market,

- **Price Range:** The difference between the highest and the lowest price.
- **Percent Price Range:** The ratio of price range to the lowest price.
- **Coefficient of Variation:** The ratio of the standard deviation to the average price.
- **Standard Deviation:** The fraction of average unit price: defined as the ratio of standard deviation to the mean unit price that is averaged across all products in a given market (Chiou and Pate, 2010, Table 4, p.302).
- **Gini Coefficient:**

$$Gini = 1 + \frac{1}{N} - \frac{2}{\lambda N^2} \sum_{i=1}^N (N+1-i) p_i$$

where p_i is the price of observation i , with $i=1,2,\dots, N$, λ is the mean price. (Gaggero and Piga, 2009).

- **Price Gap:** The price difference between the two lowest-priced firms (Baye et al., 2004a).
- **Atkinson Index:** Defined as

$$= \begin{cases} 1 - \frac{1}{\lambda} \left(\frac{1}{N} \sum_{i=1}^N p_i^{1-\phi} \right)^{\frac{1}{1-\phi}} & \text{for } \forall \phi > 0 \text{ and } \phi \neq 1 \\ 1 - \frac{1}{\lambda} \left(\prod_{i=1}^N p_i \right)^{\frac{1}{N}} & \text{for } \phi = 1 \end{cases}$$

where p_i is the price of observation i , with $i=1,2,\dots, N$; λ is the mean price; and ϕ is the choice parameter (Gaggero and Piga, 2009, p.8, footnote 14).

- **Entropy Index:** Defined as

$$= \begin{cases} \frac{1}{N} \left(\sum_{i=1}^N \left[\left(\frac{p_i}{\lambda} \right)^\phi - 1 \right] \right) & \text{for } \forall \phi > 0 \text{ and } \phi \neq 1 \\ \frac{1}{N} \sum_{i=1}^N \left(\frac{p_i}{\lambda} \right)^\phi \ln \frac{p_i}{\lambda} & \text{for } \phi = 1 \text{ or } \phi = 0 \end{cases}$$

where p_i is the price of observation i , with $i=1,2,\dots, N$; λ is the mean price; and ϕ is the choice parameter (Gaggero and Piga, 2009, p.8, footnote 14).

Explaining E-Retail Prices

The literature has documented a number of explanations for pricing issues observed in various markets, which I summarize below:

- **Branding/Reputation:** Because consumers have to submit the payment before receiving an order, trust plays a crucial role in online shopping. Naturally, risk-averse online shoppers prefer more reputable stores (Smith and Brynjolfsson, 2001). Thus, consumer awareness and sensitivity to branding allow some sellers to charge premia (Baylis and Perloff, 2002; Dinlersoz and Li, 2006), resulting in price dispersion (Chen and Hitt, 2002).⁶
- **Channel Substitution:** As sellers expand to the online channel, various coordination issues arise. While there is some evidence of cannibalization of the Internet channel in the publishing industry (Gentzkow, 2007), the actual outcome varies across product markets, and probably over time as well. For instance, Goolsbee (2001) finds evidence of channel conflict when consumers buy computers between channels; Pozzi (2013) estimates a 13% rise in overall revenue resulting from the establishment of the Internet channel by a supermarket chain, with little impact on traditional sales; Overby and Forman (2015) show that the

diffusion of online sales reduce geographic price dispersion in the wholesale used car market.

- **Competition:** The level of competition may determine sellers' pricing strategies. With only a handful of competitors, high prices can be sustained through tacit collusion. As more sellers join the competition, it would drive down the price as well as price dispersion. Evidence from various online markets suggests that competition leads to lower prices (Baye et al., 2004b; Haynes and Thompson, 2008) and lower price dispersion (Nelson et al., 2007; Gaggero & Piga, 2011). Using ticket-level data, Chakrabartya and Kutlub (2014) find an S-shaped relationship between price dispersion and market concentration (measured by inter-firm, inter-flight, and frequency competitions, respectively).
- **Consumer Heterogeneity:** The existence of consumer heterogeneity allows sellers to engage in price discrimination (Baye and Morgan, 2001; Matsumoto and Spence, 2016). For example, sellers may offer promotions (e.g., e-coupons and rebates) to attract price-sensitive consumers, while charging the full price to loyal customers (Grewal et al., 2011). In recent airline studies, Piga and Bachis (2011) identify different currencies as an effective tool to discriminate travelers residing in different regions, and Kutlu (2015) argues that limited consumer memory may also lead to price dispersion.
- **Dynamic Pricing:** Market efficiency, reduced menu costs, and effective monitoring capability allow e-retails to adjust prices fairly easily according to changing market conditions (Kannan and Kopalle, 2001; Jayaraman and Baker, 2003). Escobari (2012) and Alderighi, Nicolini, and Piga (2015) both study the dynamic pricing of seat inventories, using the U.S. and European data, respectively.
- **Oligopoly Strategies:** Profit-maximizing sellers engage in mixed pricing strategies to avoid fierce competition in the homogeneous product market (Baye and Morgan, 2001; Yan, 2008). This randomization strategy effectively prevents both buyers and competing sellers from figuring out where the lowest price is. Periodical sales are good examples. Sometimes, e-retails engage in product differentiation (Clemons et al., 2002; Ba et al., 2012).
- **Market Efficiency:** Sengupta and Wiggins (2014) study transaction data to compare airfares purchased online and offline and claim that more efficient shopping contributes to the observed lower online fares and thus greater online dispersion. In another airline study, Dana and Orlov (2014) find online purchase reduces market frictions, which in turn improves airlines' operation efficiency, defined by load factors.
- **Market Maturity:** Online sellers' pricing strategies may evolve over time. To capture the effect of evolution on firms' strategies, studies usually collect data at different points in time to examine the effect of market evolution (Pan et al., 2003). Chen's (2006) findings contrast those of Clemons et al. (2002), suggesting price convergence in the online airfare market. Taking an innovative approach, Bock et al. (2007) use data from U.S. and China to proxy different stages of e-commerce maturity. They conclude that more matured online markets are associated with lower prices and lower price dispersion.
- **Price Partitioning:** E-commerce encourages innovative pricing strategies, such as flexible price structure. One popular practice is to separate surcharges, such as shipping and handling fees, from the base price (Xia and Monroe, 2004; Gumus et al., 2013). Such a strategy allows e-retailers to further differentiate from each other. Even if they charge the same price for an

item, e-retailers may still soften competition by varying surcharges. As a result, the final price can be quite different depending on where a buyer shops. For instance, “free-shipping” with minimum purchase is an effective way to increase demand (Brynjolfsson and Smith, 2000; Dinlersoz and Li, 2006).

- **Quality:** Some studies relate price dispersion to product quality. Wolff (2015) examines the online diamond market and finds a positive relationship between dispersion and quality of these gemstones. In an airline panel study, Ater and Orlov (2015) show that flight quality (measured by both flight times and on-time performance) deteriorate as more travelers obtain Internet access.
- **Seller Heterogeneity:** Price dispersion may also be due to differences in seller types. For example, consumers may prefer MCRs to Dotcoms in terms of post-sale services (e.g., returns and exchanges). Carlton and Chevalier (2001) argue that internalization of free-riding problems leads to higher online prices at MCRs. The geographic location of e-retailers also matters in setting prices. In a cross-country study, Baye et al. (2006) find that the average price for consumer electronics sold in the Euro zone rises by 3% after the introduction of Euro in 2000. On price stickiness, Lunnemann and Wintr (2011) argue that price changes occur less often in the U.S. than the selected EU countries.
- **Taxation:** E-retailers are required by law to collect sales tax in the states where they have a physical presence (Anderson et al., 2010). Depending on the shipping address, online shoppers may pay different final prices pertaining to sales tax for otherwise an identical item from the same e-retailer. Recent studies show evidence of cross-border purchases driven by lower sales tax rates available (Ballard

and Lee, 2007; Ellison and Ellison, 2009; Hortaçsu, Martínez-Jerez, and Douglas, 2009; Goolsbee, Lovenheim, and Slemrod, 2010). Using a 4% sales tax cut in New York City as a natural experiment, Hu and Tang (2014) find Internet and catalog sales decline by 15%, although the effects vary across different types of consumers, products, and channels.

FUTURE RESEARCH DIRECTIONS

As the literature moves towards maturity, researchers began to explore new areas relating to e-commerce. Here I discuss several potential directions for future research.

As much has changed during the last decade, the literature on online price and price dispersion is in need for new evidence. It would be interesting to re-investigate the topic using most recent data, especially in the international markets. For example, Navarro et al. (2015) study online price and price dispersion of airfares on the Madrid–New York route from a new perspective, i.e., economic crisis. Furthermore, recent research has turned to transaction data (Sengupta and Wiggins, 2014; Zhao et al., 2015) and structural estimation (Baye et al., 2011; Pozzi, 2012), and still have ample room for further developments in both U.S. and overseas markets.

Understanding consumer behavior is another potential topic of interest. Future research may study consumer pre-purchase search behavior using browsing information, not self-reported surveys (Johnson et al., 2004), and then test whether the result of limited consumer search still prevails today. Understanding the competitive implications of the interactions between search and targeting online by incorporating fine aspects of consumer search (Chen and Sudhir, 2004) should also be useful. In addition, surcharges are non-refundable for rebates or price-matching requests, and, depending on the amount, such surcharges may affect consumer’s

decision regarding refund request, which in turn influences post-purchase behavior (Xia and Monroe, 2004).

Recently, the Marketplace Fairness Act, or Internet taxation, provides another potential avenue for future research. From early days of e-commerce, sales tax rates have been positively affected online purchase, with a declining effect over time (Alm & Melnik, 2005; Anderson et al., 2010; Einav, Knoepfle, Levin & Sundaresan, 2014). However, due to data limitation, existing studies focus on the impact of Internet taxation on the propensity of online purchase, future work may investigate the impact on the magnitude of online spending (Alm & Melnik, 2005).

Finally, the border between online and offline channels becomes increasingly blurry, giving the rise of hybrid operations in retailing. For example, Amazon recently launched its first brick-and-mortar bookstore in Seattle, WA, in late 2015, with more physical locations in the plan. Incidentally, China's Alibaba.com established its first physical store in Tianjin, China, in early 2016.⁷ Such a new trend in e-commerce is to provide consumers an integrated shopping environment, through which the industry has offered an avenue for further research as well.

CONCLUSION

This article presents a useful reference on recent research on Internet price dispersion, and aims to better prepare various interest groups for future challenges and opportunities in the new economy.

KEY TERMS AND DEFINITIONS

Integrated Shopping: E-retailers establish physical stores as a way to enhance shopping experience of their customers.

Load Factor: Or passenger load factor, is often used by airlines to measure capacity utilization of their fleets.

Multichannel Retailers: Retailers conduct businesses through multiple distribution channels.

Price Discrimination: Firms charge different prices to different consumers for an identical product.

Price Dispersion: In a homogeneous product market, prices charged by different sellers are different.

Price Partitioning: Retailers divide the total product price into different components – a base price and surcharges including shipping and handling, taxes, and other fees.

Shopbot: A useful online search tool helps shoppers collect product information.

The Marketplace Fairness Act: A pending proposed legislation requires e-retailers to collect sales tax regardless of physical location.

Social Commerce Using Social Network and E-Commerce

E**Roberto Marmo***University of Pavia, Italy*

INTRODUCTION

Social network is an online media that supports social interaction in real life. E-commerce regards buying and selling of products or services conducted over internet and other computer networks. While traditional E-commerce supports the transactional and informational aspects of online shopping, Social Commerce fulfils the social aspects of shopping. Combining the advantages offered by social network and e-commerce, it is possible to create a web business platform to generate and increase revenue by turning web visitors into customers. Social Commerce involves social media and user contributions to assist in the online buying and selling of products and services, to design and deliver better customer experiences with the help of technology. This chapter describes some technologies that can help define Social Commerce, it also discusses background, knowledge, challenges and critical factors necessary for successful business. Future trend are described.

BACKGROUND

Social Network is a social structure composed of individuals, organizations, company etc. which are connected by relationships and interactions. Web-based social networks are online communities that allow users to publish resources (personal data, photo, video, blog) and to establish relationships of a different type about business, entertainment, gaming, dating, etc. Usage and diffusion of social networking platform has been

increasing, with hundreds web platforms in the world collecting the information of more than one billion registered users. Therefore, today social networks are used intensely to communicate, share information, make decisions, and do business in many ways. Well-known social networking websites are: Facebook as generic social network, LinkedIn and Viadeo as business social network, Flickr about photo sharing and Google+ as solution from Google search engine. Thus, online social network is a relevant part of human life (Fu, Chen, Liu, & Wang, 2007; Goth, 2008) and it is truly the reflection of today's society.

Consumers generally want to ask their friends or experts about a shopping decision or want to share their new purchase with friends; therefore, conversations regarding shopping happen all the time. Consumers generally are communicating with each other via social network. For selling message and open up new sales opportunities, it is necessary to resound with customers and to take advantage of their social network channels by interacting with them, in order to send business messages to customers and their friends.

Electronic commerce, commonly known as e-commerce or eCommerce, is a type of industry where the buying and selling of products or services is conducted over electronic systems such as internet and other computer networks. E-commerce is not only limited to online sales, but also covers: real-time management of product availability, online payment, delivery tracking and after-sales service. E-commerce sites are online stores which have at least the following elements at the front-office (customer) level:

DOI: 10.4018/978-1-5225-2255-3.ch249

- Electronic catalog listing all products for sale, price and availability;
- Search engine to easily locate a product using search criteria;
- Virtual cart, to trace the purchases of the client along the shopping path;
- Secure online payment via secure transaction;
- Order tracking system.

A back-office system allows the online dealer to organize electronic catalog, modify prices, add or remove product, handle client orders.

SOCIAL COMMERCE AND SOCIAL SHOPPING

Social Commerce is a subset of e-commerce that involves using social media, to connect, listen, understand, and engage people to improve the user shopping experience and to assist in the online buying and selling of products and services. In other words, these applications merge online shopping and social networking (Tedeschi 2006). The social commerce website are sites designed specifically to support social interactions while online consumers shop.

This is the latest solution to a chronic problem for online retailers and shoppers: many shoppers aren't sure what to buy, but they know they won't find it on the sites of mainstream retailers (Tedeschi, 2006).

Social Shopping is another frequent synonyms, but Social Commerce regards online sellers combining social network and e-commerce, social shopping regards collaborative activities by online shoppers. Social Shopping regards how customers use a social commerce website to shop, so it plays to a natural extension of our everyday behaviors, where we go shopping with friends, seek advice from friends and then decide based, at least in part, their feedback. In other words, the distinction

between Social Shopping and Social Commerce is that while social shopping connects customers, Social Commerce connects sellers and customers (Andrew, 2010).

The online shopper can be examined as a prospective user of an emerging social commerce platform. It is the concept of word of mouth from social media marketing (Singh, 2012), aligned to e-commerce.

The term Social Commerce was introduced by Yahoo! in November 2005 (available on line at www.ysearchblog.com/2005/11/14/social-commerce-via-the-shoposphere-pick-lists/) to describe a set of online collaborative shopping tools such as shared pick lists, user ratings and other user-generated content-sharing of online product information and advice. Important dates about history of Social Commerce are visualized at website http://socialtimes.com/social-commerce-infographic-2_b84120.

Social Commerce gives retailers opportunity to leverage benefits of interacting with consumers, discussing directly goods and their features, spreading information about retailer. Within this framework, customers have access to social knowledge and experiences to support users in better understanding their online purchase purposes, and making informed and accurate purchase decisions (Dennison et al. 2009).

A systematic analysis to 64 papers is discussed on (Salvatori, 2014), to summarize the existing evidence concerning the social commerce and outline some open challenges.

Social Principles

Social psychology explains that there are rules that people follow to navigate the decisions that need to be made. Six principles of influence that human beings use in decision-making can be identified (Cialdini, 2006), so it is possible to identify six social principles that can drive sales to Social Commerce success:

1. **Scarcity:** Less is more is perceived as more valuable, so offering limited-time discounts, items with limited availability, limited access and exclusivity;
2. **Affinity:** Shoppers are likely to buy items that friends or VIP figures have recommended;
3. **Reciprocity:** Shoppers are more likely to buy items that they have sampled;
4. **Popularity:** Shoppers follow the crowd, so they are likely to buy an item with reviews or higher ratings;
5. **Authority:** Shoppers are likely to purchase an item recommended by a leader or an expert;
6. **Consistency:** When shoppers aren't sure about a shopping decision, they do what they have been doing based on their buying history.

Tools about social activities can allow sharing the user shopping experience:

- Ratings;
- Recommendations;
- Forum;
- Group buy;
- Purchase sharing.

Online shopping is a voluntary and hedonic activity, and users participate because they are intrinsically motivated. The experience often offers entertainment and fun, which users have been found to appreciate (Mathwick, 2002).

Main Steps

There are main steps in successful Social Commerce strategy:

1. Searching information about product through tags, bookmarks, keywords, ranking created from other people on social network, blog, other websites;
2. Purchasing from sellers who are linking the social presence with e-commerce site, the

online transaction and payment systems are based on e-commerce platform;

3. Sharing information that comments or recommendation the shopping experience with other people, adding social features such as social plugin by Facebook platform.

In this way, it is possible to apply word-of-mouth to e-commerce, by sharing purchasing decisions before, during and after buying. Solutions exist for brands large and small, making their products more available and more convenient for customers.

Customer's roles vary across platforms and can range from only customer, customer generating content (e.g., product reviews and recommendations, consumer-generated media) to being sellers and curators of online stores.

A practical road map for monetizing Social Commerce investment is required. A strong and measurable strategy, a sort of social action business plan, can be obtained in this way:

1. Understand social networks, social business and Social Commerce;
2. Define current status quo, desired goals, timeline;
3. Set up e-commerce web site reached by links from social networking platform, or set up social network pages with e-commerce module;
4. Define your customers, exploring demographics of your target market and learn where and how customers are communicating with each about buying decisions;
5. Build customer base through social media marketing and appropriate use of most popular social networking platform that appeal to your target audience to full advantage;
6. Define promotional schemes so that users recommend other;
7. Define which social platform works for which objectives, define creative ways to share buying content;

8. Choose between popular social networking platforms or specific platform for social commerce;
9. Optimize social network pages to attract clicks and customers;
10. Monitor online reputation, how seller is viewed by customers, addressing contents which are damaging to business;
11. Measure results closely as any other marketing activity;
12. Improve customer service;
13. Learn from the mistakes of others.

Regarding (3), here are two technical strategies: social media on e-commerce platforms, e-commerce on social media platforms. First case regards helping people connect where they buy. It is necessary sharing purchase information across the open web and social network by placing in e-commerce products pages social plugin provided by Facebook: share, like and recommendation buttons. Also, integration with chat is desirable, so friends can shop together and buyers can talk with vendor. Second case regards the availability of e-commerce platforms which makes it possible to buy without leaving the social network they are using to talk to their friends, such as e-commerce tab on Facebook Page.

Regarding (8), on the internet there are online services created specifically to make Social Commerce, traditional social networking platforms have been created for different purposes and were later adapted for Social Commerce.

Regarding (9), some suggestions about most popular social networking platform are explained in following sections.

Regarding (11), as a positive result of investment, a seller wants to increase traffic, conversion rate (percentage of website visitors who buy something on the site) and average order value. Return on Investment (ROI) measures the effect or action of social media on sales, that is, as formula: gain from investment/ cost of investment. A high ROI means the investment gains compare favorably to investment cost. It is hard to evaluate and measure

the benefits brought by social commerce especially from financial perspective (Jussila et al, 2011; Turban et al, 2010). As example, a Facebook Page of company has successfully attracted 1,000 visitors to its e-commerce website after implementing social commerce in its business, but this performance indicator can only demonstrate that 1,000 people know information about the company and its product, there is no guarantee that all or part of them will turn into buyers.

The number of likes on Facebook Page and number of post shared between friends are not particularly meaningful to calculate ROI. In order to track results, it is necessary to define and measure key performance indicators as follows: analytics from popular social networking platform such as Facebook Insights which provides developers and Page owners with metrics about their content, how many users recommend other users, traffic coming from recommendations, sales coming from recommendations.

By understanding and analyzing trends about usage and demographics as well as consumption and creation of content, sellers can be better equipped to improve business and create better experiences on Facebook.

Regarding (12), in order to create a business connection which leads to sell, each seller must listen and quickly respond, handling service issues instantly using social networks. In this way, customer service initiatives can be named as Social CRM (Customer Relationship Management), the next frontier for organizations that want to optimize the power of social interactions to get closer to customers.

Below some technologies that can help business based on social commerce are introduced.

Facebook Page

Facebook is the most popular online social networking service. F-commerce is derived from e-commerce, suggests the use of Facebook as a platform for facilitating and executing sales transactions, either on Facebook itself or exter-

nally using Facebook Open Graph. Online floral retailer 1-800-Flowers has the first online store on Facebook at 11.50 a.m. July 8, 2009.

Facebook provides the Page to build a closer relationship between sellers and customers, as detailed on www.facebook.com/about/pages, it also allows to create global pages with regional featured products. The online store created on Facebook Page lets customers shop and complete purchases without leaving Facebook. An example regards Blomming, a personal Social Commerce made by humans, easily discover and shop unique items in an always updated marketplace, in www.facebook.com/blomming using tab Demo Shop available under the cover photo.

Some suggestions about best business practices using Facebook Page:

- Publish limited-time offers via wall and tabs;
- Highlight a product that appeals to a large number of fans;
- Use photo tab to showcase product images and a gallery of related products;
- Use wall and status updates to post product information, pin a new post to the top of page each week so people notice what's important, attach an image of the product that appears in fans' wall;
- Include a link in every post, so interested users can directly go to the point of purchase;
- Give users a voice to comment on the items they like best, encourages conversation around product on the wall;
- Create tabs to offer an incentive suitable for fan base growth, such as to provide exclusive offers to its fans who clicked on the button Like;
- Allow users to state preferences on products by creating polls in which users can vote for their favourites items;
- Provide users the power to express themselves creates a feeling of value, such as allowing download and publications of photo.

As described on a study about Thai consumers' intention to buy toward Facebook commerce is described on (Suraworachet, 2012), belief in people who like a Facebook Page, belief in people who like a photo of an item on e-commerce catalog and belief in friends who like a Facebook Page have significant impact on consumers' attitude.

Furthermore, attitude and perceived ease of use also have a significant effect on consumers' purchasing intention on e-commerce inside Facebook.

Pinterest

Pinterest is a pinboard-style photo-sharing website that allows users to create and manage theme-based image collections. Pinterest has found an optimal balance between inspirational browsing and shopping, making an effective distribution channel. It is possible to create branded pages for brands, stores and boutiques. If users are already discovering products through Pinterest but going off to merchant sites to transact, Pinterest should own that transaction and offer a consistent user experience. Pinterest offers a separate shopping channel (shop.pinterest.com), useful to focus on commerce.

Twitter

Twitter is an online social networking and micro-blogging service that enables users to send and read tweets, which are text messages limited to 140 characters. Twitter feed can be used to promote an individual product or to drive traffic to e-commerce website. It is useful to provide offers within time-sensitive campaigns. Optimizing times when the greatest number of followers see a tweet is critical to garnering the largest number of impressions. 140 character limit for each tweet requires to make offer and product descriptions short and direct. Checking out popular niche hashtags it is useful to find top influencer (a person who has upwards of a few thousand followers) related to keywords that describe product for sale. The influencer can tweet to their followers about e-commerce web

pages, this approach can drive a lot of people to check out what they're recommending and even make a purchase.

YouTube

YouTube is a video-sharing website. It is best served for creating awareness and interest about a campaign and initiatives. Some suggestions to create a video that encourages purchases: video can describes product manufacturing, video can suggests how to use an object, it is possible to create a branded channel, video can addresses a consumer pain point including music or comedy and paying attention to the open and close. It is important to place links within a video to suggest the path to point of purchase. By embedding videos outside of YouTube on the web it is possible to create a viral brand experience reaching many customers.

ISSUES AND PROBLEMS

The main doubts that must be discredited are that Social Commerce users are not in a mood for shopping when they socialize. Issues like privacy and fair use of data pose a formidable challenge, so the question regard whether Social Commerce is disruptive or intrusive. Social Commerce requires a wide variety of information to target and promote products, it requires analysis of customer preferences and tastes, it is not always possible to obtain similar information due to privacy setting and lack of data. Credit card safety and prevention of online fraud are also relevant problems, such as traditional e-commerce. Social networking platforms are not feeling with information and privacy security, so it is necessary a special effort to create a store where the user can buy with confidence and without getting in trouble.

A model that captures the essential features of the Social Commerce business is described in (Kim, 2013) to see whether Social Commerce is sustainable, and discuss conditions for stable evolution of the industry. The model is investigate

about the possibility that the tragedy of commons occurs in the industry due to an excessive competition in market share.

Predictable products like books, CDs, and electronics can be bought easily. But fashion lagged behind. Also in case of recommendations and suggestions from friends, consumers want a tactile, in-person experience when it comes to garments.

User graphic interface play a relevant rule, adding social tools requires re-design the web page and pay attention to create visual form having more buttons, icons, link ecc. So, customer can lose attention, feel confused and he rapidly moves to another website.

The price fairness perception had a significant influence on the repurchase intention. The illusion of control did not play a significant role in the point that the Social Commerce buying experience affected the price fairness perception. As a result of analysing the influences (Kim, 2013) on the price fairness perception by classifying the types of price fluctuations, there was a significance influence only in case of unfavourable type to consumers.

SOLUTIONS AND RECOMMENDATIONS

Sellers are directly connected by online social networks with customers, so today sellers are perceived as individuals instead of firms. Social Commerce cannot be arranged using only internet technology, because it concerns people influencing people in case of shopping online. Therefore, it is necessary to acquire skills on science of human relationships and social psychology that deals with how people think about, influence and relate to one another (Goleman, 2007).

Trust is particularly important in Social Commerce transactions, due to the difficulty of taking legal action in cases of dispute or fraud and the potential for conflicts caused by differences in culture and business environments. Trust is usually about trusting of recommendations from

friends and from other consumers. To deal with these issues, sellers need to establish high levels of trust with current and potential customers (Turban, 2012).

Therefore, sellers must be conversational, involving nurturing relationships, building long-standing trust with customers. In this way, it is possible to gain more prospects, convert them into buyers, and foster them as brand advocates for your business.

Today, mobile device is playing a much greater role in the average shopping experience (Hayden, 2014). To capitalize on immense m-commerce (mobile e-commerce) opportunity, sellers must develop an application (app) or specific version of website for mobile device, possibly including mobile payment solutions.

Each seller must help customers to promote his brand as they recommend products and services to their friends on preferred social networks, absolutely necessary to give to customers opportunity to share information about product with their social media contacts.

A social network between sellers in a large online Social Commerce marketplace can create a virtual shopping mall, because each seller creates his or her own shop, and network ties between sellers are directed hyperlinks between their shops. Allowing sellers to connect generates considerable economic value, the network's value lies primarily in making shops more accessible to customers browsing the marketplace, and the sellers who benefit the most from the network are not necessarily those who are central to the network but rather those whose accessibility is most enhanced by the network (Andrew, 2010).

In order to mitigate the risk of disrupting and irritating users who do not want to participate in social networks, a separate shopping channel is desirable to be adopted by this kind of user.

Shopping recommendation to customers can be based on style and preferences, these recommendations are computer generated, some are handpicked by friends, etc.

The design of a Social Commerce website should implement effective local social network features to connect with and engage its users, mediate their identities, and empower them in this rising participatory culture (Sun, 2006).

A model and a set of principles for Social Commerce design are introduced and design features are summarized as: usability, information quality, website quality, service quality and playfulness. The proposed and justified Social Commerce design model are based on: Individual, then Conversation, then Community, then Commerce. A specific table lists the design features as they apply or not to two target Social Commerce websites: Amazon and Starbucks Facebook.

As suggested in (Huang, 2013) management needs to identify its existing e-commerce and social networking applications and capabilities. They must then decide on the way to develop their Social Commerce strategy: to add social features to their e-commerce platform, or to add commerce features to their social network platform.

FUTURE RESEARCH DIRECTIONS

As Social Commerce scales, the biggest challenge will be surfacing signal buried in noise, so it is necessary new trend to create relevant content, newsfeed about shopping, specific guidelines for user interface design.

Technologies such as augmented reality will be combined with Social Commerce, allowing shoppers to visualize fashion items on themselves and solicit feedback from friends.

Future and emerging trends regards research model for investigating the impact of online communication of consumers, which produce social word of mouth on trust building mechanisms, increasing the level of trust on new products (Hajli, 2013).

One of the main reasons for participating in Social Commerce is to share and exchange information about shopping with other users.

Challenging issue regards framework to protect private information on social network (Carminati et al, 2009) and developing social customer relationship software taking care of privacy.

Social networking giants will develop competitive technological features to provide e-commerce in their platforms, in order to obtain a percentage of the price paid when a user of the social network buys something.

Technologies such QR codes and geo-tagging will bring social commerce to street commerce using mobile device.

Recommendation aims to recommend products from e-commerce websites to users at social networking sites in coldstart situations, a problem which has rarely been explored before. A major challenge is how to leverage knowledge extracted from social networking sites for cross-site cold-start product recommendation.

CONCLUSION

Today's consumer relies on input from a trusted community when making buying decisions, generally are communicating with each other via social network. Social Commerce is a business phenomenon that needs to be better understood, because it power commerce and drive sales combining social networking and e-commerce online platforms. This approach involves a lot of problems, so determining relevant factors and effective strategies to utilize social network for all kind of sellers is no easy.

Social Commerce, if approached properly, can be an extremely effective tool when it comes to the success of business, because it helps to boost e-commerce website traffic, reach out to a wider audience in shorter time and lower cost, increase brand awareness and it can increase product sales.

Due to wide variety of methods and strategies proposed which can be adopted, companies should look out for challenges and plan well when adopting social commerce into their existing business.

With new and upcoming technologies, the biggest change for Social Commerce marketers will be a shift in focus from branding to lead generation. they also ease the sales process by providing ways to effectively interact with customers.

KEY TERMS AND DEFINITIONS

E-Commerce: Buying and selling of products or services conducted over internet and other computer networks.

Influencer: People who potentially have the power to convince others to stay or switch to other brand.

Mobile Social Commerce: Integration of social media with e-commerce on mobile platforms.

Social Commerce: An emerging approach of e-commerce that involves using social network to supports social interaction, to assist in the online buying, to facilitate discussion between seller and between buyer and seller or buyer and his friends.

Social CRM: The integration of social media into customer relationship management as tool focused on optimizing customer lifetime value.

Social Media Marketing: The process of gaining website traffic or attention through social media sites. Social media marketing programs usually center on efforts to create content that attracts attention and encourages readers to share it with their social networks.

Social Network Analysis: Mathematical technique developed to understand structure and behaviour between members of social system, to map relationships between individuals in social network.

Social Networking: Grouping of individuals into specific groups or communities.

Social Shopping: A natural extension of our everyday behaviors, where people go shopping with friends.

Trust: Psychological status of depending on another person or organization to achieve a planned goal.

Word-of-Mouth: Passing of information from person to person by oral or written communication.

An Update on Bitcoin as a Digital Currency

Cecilia G. Manrique

University of Wisconsin – La Crosse, USA

Gabriel G. Manrique

Winona State University, USA

INTRODUCTION

“The Evolution of Virtual Currencies: Analyzing the Case of Bitcoin,” a manuscript co-authored by Cecilia G. Manrique with Gabriel G. Manrique was recently published as a chapter in the book *Information and Communication Technologies in Public Administration*. It was written at the height of the recent bitcoin controversy when its value (in relation to the US dollar) underwent wild swings. It has been more than a year since the research for that chapter was conducted, and much has transpired since then affecting bitcoin’s acceptability as a virtual currency. It is the purpose of this paper to present an update on the status of bitcoin as a currency and to determine its stability and ability to become a real one.

This chapter will consist of four parts: a background based on a previous work, a review of what has been written about the topic to date, an update on the current status of bitcoin, and a future trends outlook on the acceptability of bitcoin as a currency. It is the purpose of this entry to shed further light on what has transpired regarding bitcoin since its very volatile and controversial period in 2013-2014 and to extrapolate on its possible future directions. Much of the controversy surrounding bitcoin at that time stemmed from several factors: its level of acceptability as a medium of exchange which is a crucial element for any aspiring currency, real or virtual; its various uses some of which had been said to facilitate criminal enterprises such as Silk Road; and its lack of stability raising questions about its suitability as a store of value. In its early stages,

bitcoin was applauded as a new and innovative currency because it could serve as a medium of exchange and a store of value with no bank and government intervention. By 2013 however, its reputation and seeming potential were ravaged by scandal, theft and turbulent prices. Has anything changed since then to restore the luster of bitcoin?

BACKGROUND

This encyclopedia entry comes on the heels of a recently published chapter entitled “The Evolution of Virtual Currencies: Analyzing the Case of Bitcoin” published in the book *Information and Communication Technologies in Public Administration*. The research and writing for it took place at the height of the bitcoin controversy. At that time in 2013-2014 the value of bitcoin skyrocketed and waned at such a volatile rate that it made for good fodder to many newspaper and magazine articles. In the month leading to bitcoin reaching its highest value

vis-à-vis the US dollar of \$1147 on December 4, 2013, bitcoin tripled in value only to decline to \$830 a month later, a decline in value of more than a quarter. By early April 2014 bitcoin had lost another 47%. As of this writing, bitcoin’s value seems to have settled in the \$250 range (BPI, 2015).

The Manrique and Manrique chapter took a look at the evolution of virtual currencies and focused attention upon bitcoin. It studied the case of bitcoin in terms of its potential as a legal tender taking into consideration the various char-

DOI: 10.4018/978-1-5225-2255-3.ch250

acteristics that make for what would constitute legal tender in society. The positive and negative impacts of transacting in bitcoin were laid out. A description of the international exchanges that bitcoin engendered was also provided. But more importantly the chapter explored the direction that regulation might take. At that time regulatory agencies and groups were just at the early stages of “thinking about” what needs to be done and were not ready to recommend, let alone enact, rules on virtual currency including the regulation of bitcoin. Thus the chapter concluded with some of the areas of research that would provide fertile fields for further research (Manrique & Manrique, 2015).

Literature Review

As a result of the expansion of, and accompanying controversies associated with virtual currencies in general and bitcoin in particular, many books about virtual currencies have been written and reviewed. A discussion of a few of those books and articles will take place in the next few paragraphs.

Bitcoin as a payment network or digital currency was said to have been developed by a person (or group) that goes by the name of Satoshi Nakamoto. A 2008 work attributed to him laid the groundwork for the first specification and proof of what the bitcoin concept was all about. (Nakamoto, 2008) If one were interested in the technology behind bitcoin one can consult the work by Menezes, et.al, which is a handbook on cryptography describing the process of turning ordinary information into hidden language that needs some code to decode it and make it readable again. Although it does not apply the theory to bitcoin since it was written before the conceptualization of bitcoin itself the reader will gain an understanding of the technology that goes into the way transactions are undertaken using virtual currency (Menezes, 1996)

It is estimated that in 2014 alone about 200 pieces had been written about cryptocurrency and that dozens more will have appeared in 2015.

Many of them are geared towards the basics of understanding the bitcoin phenomenon because they are “befuddled” (Barski, 2014) while others are written for the beginner who would like to dabble in bitcoin transacting. (Franco, 2014) Several column pieces have been published by the Wall Street Journal and the Economist over the past year that give one a good impression of the direction the discussion has been going. And a television special on bitcoin was hosted by Morgan Spurlock as recently as early 2015. The Spurlock television special takes a very elementary look at bitcoin and provides background but not much more to the serious researcher. It serves the purpose of exposing the general public to the existence of virtual currencies, their uses and the possibility of adoption in the foreseeable future. Thus it serves an educational purpose by bringing a new and innovative topic to the attention of the ordinary citizen. (Spurlock, 2015)

Two of the books that have been written about bitcoin are entitled *Digital Gold* written by Nathaniel Popper and *The Age of Cryptocurrency: How Bitcoin and Digital Money are Challenging the Global Economic Order* by Paul Vigna and Michael Casey, two writers whose articles in the Wall Street Journal served as sources for much of the research that went into the original Manrique and Manrique chapter.

David Kushner’s review of *Digital Gold* in the Wall Street Journal takes a look at the nefarious characters that Nathaniel Popper writes about in his “inside story” about the misfits and millionaires who have tried repeatedly and extensively to re-invent money with their support of virtual currencies but more specifically of bitcoin. Kushner wrote that the cast of characters portrayed by Popper may have a tendency to turn off readers to the possibilities of virtual currencies because the portrayals tend to focus on the machinations of the bitcoin underworld. Prominent among the characters accounted for in the book is Ross Ulbricht who was responsible for building Silk Road. Silk Road is considered by many as the largest black market site on the web where transactions

on drugs and drug-trafficking, money laundering, and other criminal enterprises were widely being undertaken. The criminal network activity in Silk Road used two main elements: Tor which promotes “anonymity online” via its free software and open network that prevents the tracking of browsing and website visits; and bitcoin which is the digital equivalent of unmarked banknotes (Bitcoin Buccaneers, 2015). Eventually, the criminal activity that took place in Silk Road was investigated and prosecuted by federal authorities, regardless of where the criminal activity took place. A federal jury convicted Ulbricht in February 2015 and in May sentenced him to life in prison.

Aside from Ulbricht, Kushner focuses on Popper’s choice of the Winklevoss brothers, Cameron and Tyler, as major players in the unfolding cryptocurrency drama. The Winklevoss brothers were involved in a lengthy legal dispute with Mark Zuckerberg over ownership of the idea for Facebook. They have since invested a good portion of their share of the Facebook settlement in bitcoin giving them claim to approximately 1% of all bitcoins in the market. For Kushner the rest of the cast of characters in the bitcoin saga based on Popper’s book remains basically the same and does not bode well for bitcoin’s hoped for role as the global change agent that it was advertised to be. What the developments and the players in the financial markets show is that the evolving “digital cash system is beginning to resemble the old one” (Kushner, 2015).

In *The Age of Cryptocurrency*, Vigna and Casey present a more optimistic view of the cryptocurrency’s role in the financial system. In fact they seem to indicate that beyond the virtual currency itself, venture capitalists supporting bitcoin are interested in how the blockchain technology behind bitcoin can be used to track various forms of financial transactions and asset transfers cheaply and securely. It has great potential to impact the financial world. Blockchain can be likened to a permanent accounting ledger that keeps track of all transactions associated with bitcoin. The potential for applying blockchain technology to different

kinds of transactions serves as a “foundation for a growing number of startups” (Vigna and Casey, 2015). While some may see this development as undermining existing financial institutions, Vigna and Casey see positive developments in the concurrent evolution of bitcoin and other cryptocurrency technology alongside existing financial institutions and businesses. This may portend a revolution or evolution in the internet of things and the internet of values.

Other works such as that of Miers, et. al. looks at alternatives to bitcoin as a result of the security problems encountered with its use. Zerocoin, according to them, serves as such an alternative, and maybe even a better one, because of the anonymity and privacy it provides. (Miers, 2013)

UPDATE

More than a year has passed since the authors researched developments in bitcoin. Since then, while much has transpired, it appears that issues surrounding those which seemed controversial at the time, have since calmed down. One of those major concerns, the volatility of bitcoin’s value, has been reduced by the relatively smaller range within which bitcoin traded during the first 6 months of 2015 compared to its trading range in the first six months of 2014 - 75% v. 167% (BPI, 2015). This section of the chapter provides an update on the status of bitcoin as a currency and its suitability and ability to become a legitimate currency. It focuses on the accompanying blockchain technology which is deemed to be the future in value-exchange protocol just as TCP/IP was for communications protocol.

Bitcoin possesses useful qualities that one looks for in a currency: it is hard to earn; it is limited in supply; and it is easy to verify. Likewise its stability and reliability are very important. It therefore caused tremendous anxiety in the market when Bitstamp (a bitcoin exchange) reported that 19,000 bitcoin units had vanished from the exchange due to a hacking attack. This led to a temporary halt

in trading and immediately brought into question the stability and reliability of the virtual currency (The Magic of Mining, 2015).

However, those optimistic about bitcoins are betting that the technology behind it called blockchain, which makes it difficult to hack, is where the future lies. To hack blockchain would require owning 51% of bitcoin's computing capacity which would be prohibitive in terms of hardware, software and electricity used. One estimate of these costs is at least \$425M (Magic of Mining, p. 58). Furthermore the energy used to support the tremendous computing power bitcoin operations entail is being generated in Inner Mongolia where energy costs are low due to poor compliance with environmental regulations. This relatively inexpensive source of energy for computing power is another advantage bitcoin has over would-be hackers. However, one must recognize that there is always the possibility that a government recognizing its monopoly power can takeover in Inner Mongolia and potentially make things difficult and expensive for bitcoin users everywhere.

Despite its problems bitcoin cryptocurrency technology is still the fastest growing sector in the Information Technology (IT) industry. Now that bitcoin's breakneck speed of growth and development may have ended and seems to have leveled, there appears to be a consensus forming among its proponents, and a resulting code of conduct among developers, that will tend to block radical changes to the current structure of bitcoin technology. It is inevitable that there will be break away developments in bitcoin. (Athey, 2016) Those who attempt such would most likely be connected to bitcoin via bitcoin blockchains – in essence forming sidechains allowing for continued experimentation and expansion from the original structure. Likewise there are those who are working towards private, permissioned blockchains veering away from the original public, permissionless ones developed for bitcoin. Adding that layer of privacy can make more adapters of the technology feel better about its security. (Bheemaiah, 2016)

Thus there seems to be two trends developing: one is the growing acceptability of bitcoin as a currency beyond just the early enthusiasts; and two is the growing usefulness of blockchain technology outside of its use in cryptocurrency to other areas not envisioned before. These are the topics of the next few paragraphs.

Bitcoin as Currency

As a currency one can see the growing acceptance of bitcoin in the market place. It is estimated that more than 100,000 institutions now accept bitcoins as a means of undertaking transactions. Businesses accepting bitcoin include Time and “Microsoft in select marketplaces, in the Windows Store, or in stores that house Xbox Games, Xbox Music or Xbox Video” (Hernandez, 2014). Dell has announced that Bitcoin would be accepted as a payment method for dell.com technology purchases. And UK merchants accepting bitcoin can be found in <http://bitcoinacceptedhere.org.uk/> while products and places where bitcoins are accepted can be found at <https://www.cryptocoinsnews.com/tag/bitcoin-accepted-here/>.

Amagi Metals has been accepting bitcoin since 2012, and cryptocurrencies comprise roughly 30-40% of its business, which is all done online, so it is already further along towards being a complete bitcoin business than most other retailers. And it is in 2017 that the owner of the business indicates that it will turn away business that is transacted in dollars and those not transacted in bitcoin.

St. Petersburg, a city on Florida's west coast, is slowly becoming a bitcoin hotbed, with its growing affection for the cryptocurrency. The St. Petersburg Museum of History has started to accept payment in bitcoin, the first in the state to accept the cryptocurrency. Going hand-in-hand with that is another prominent bitcoin-related event in the area: the 2014 Bitcoin Bowl – formerly known as the Beef O' Brady Bowl which was meant to boost bitcoin's acceptance in the city (Vigna & Casey 2014a).

Other uses of bitcoin have been in the realm of charitable giving. In 2013, immediately after Typhoon Yolanda struck the Philippines, the charitable organization Save the Children began accepting donations via BitPay, a company that processes the donations. Bitpay converts the bitcoin gifts into dollars thus avoiding the uncertainty over price volatility. The use of Bitpay is also advantageous for both donors and recipients especially for those accepting small gifts of a few dollars or less because there are no transaction fees incurred. This is unlike donating using credit cards where transaction fees may be charged. The American Red Cross and Green Peace are also engaged in the growing acceptance of the cryptocurrency. Its usefulness in the non-profit sector is tremendous because transactions can carry lower costs than credit or debit based payments. It thus attracts a whole new pool of givers (Silverman, 2015).

The development of San Francisco based 21 Inc. which has accumulated the largest investment by a startup in the digital currency sector has bolstered confidence in the future of bitcoin. It is named after the 21 million limit of the bitcoin algorithm that determines how much bitcoin is released into the system. Its goal is to come up with software and hardware products designed to drive the mainstream adoption of bitcoin (Casey, 2015a). Widely-recognized and respected names such as Lawrence H. Summers, former Treasury Secretary, joined 21 Inc.'s advisory board. Cisco Systems invested an undisclosed amount in the company for a line of chips for smartphones that will be able to "mine" the digital currency (Heavy Hitter, 2015). Goldman Sachs, JP Morgan Chase and Co., Yuan Capital, Qualcomm Inc., eBay Inc., Dropbox Inc., Expedia Inc., and Zynga Inc. are just some of the companies that are honing in on the new technology that can come out of the heavy investment in cryptocurrency technology.

Blockchain Technology

Followers of developments in this area are especially excited about the potential of blockchain

technology. It can eventually be used to support important new uses in transactional activities such as lawyer-free smart contracts to tamper-proof online voting systems (Casey 2015b, C2). This can lead to the further development of the "Internet of things" and the "internet of value," terms which have been used to describe the "myriad smart, internet-connected apps communicating with servers, networks and each other in order to optimize their operation, maintenance and energy usage without direct human intervention" (Casey, 2015a).

It will bring bitcoin into the realm of a mass-marketed phenomenon. In the financial transactions sector, private companies typically handle the transfer and sales of shares with information systems that use spreadsheets maintained by lawyers who verify transactions by hand. If such were replaced by the process based on bitcoin's blockchain technology it would mean real time settlement instead of waiting a few days for transactions to be verified and cleared. This can reduce the risk of counterparty failure and free up billions of dollars that are sidelined during the waiting period. With bitcoin technology getting the Nasdaq nod by the appointment of a "block chain technology evangelist," Fredrik Voss, Nasdaq takes the lead in efforts to increase the use of such technology in the NY Stock Exchange (Hope and Casey, 2015a). It is possible that other exchanges will follow suit.

Blockchain technology and the increasing acceptance of Bitcoin will likely transform how people buy and sell goods and transfer money across the globe. However, bitcoin's limited use beyond the 100,000 products and places that accept them still needs to be addressed. And it is thought that much of the reluctance in its adoption is because of security concerns, criminal usage, and price volatility issues. It is difficult to trade in bitcoin if there are not enough buyers and sellers at exchanges. It will require more interest from institutional investors including hedge funds and proprietary traders. Liquidity is also widely scattered across exchanges in HongKong, Europe and

the United States. It is said that for firms to get engaged what will be required are more sophisticated infrastructure which 21 Inc. investment hopes to address (above) and regulatory clarity and certainty which has been paved by New York state (Hope and Casey, 2015b).

Bitcoin got another boost in July of 2014 when the New York State Department of Financial Services released a proposal to regulate digital currencies in the state. It got greater strength when in June of 2015 the regulation was finally approved. It is the first of its kind in terms of the regulation of virtual currencies for those operating in the state of New York. Pertinent aspects of the regulation affect those that exchange virtual currencies for dollars. They have to apply for a license; have to engage in reporting; and comply with rules regarding customer/consumer protection, anti-money laundering, capital adequacy, change of ownership and cyber security (Casey, 2015a).

Such regulations have both supporters and protesters. Supporters applaud these regulations as an opportunity to bring credibility, legitimacy and confidence to a six year technology marred by concerns about security and criminality. Protesters decry the regulations as the state's clumsy attempts that will cause emerging technologies in this area to be "doomed even before they get out of the cradle" (Casey, 2015a).

However in the natural evolution of things, the bitcoin phenomenon will lead to all kinds of linked cryptocurrencies and blockchain uses as stores of value, means of exchange, mechanisms for transferring assets and verifying transactions – all functions of a legitimate and accepted currency which can still be found in bitcoin. But more than the currency aspect, bitcoin has unleashed a wave of financial innovations, considered a new branch of the IT industry which is not yet fully understood in terms of the other rising uses of blockchain technology: transacting in other assets such as stocks and bonds and/or notarized e-messaging. Eventually, it may be that bitcoin's value is not so much as a currency but in the block chain technology it has spawned.

It is therefore likely that bitcoin acceptability as a currency will continue to grow but at the same time newer, more innovative uses for the blockchain technology that goes along with it will be discovered and developed thus taking advantage of this growing field.

FUTURE RESEARCH DIRECTIONS

It is very interesting to monitor the evolution of a concept and a reality in a cryptocurrency like bitcoin. It is certainly something that warrants continued monitoring since it seems to be gaining acceptance now. It may not completely replace the dollar but its technological value especially in business and finance in the age of mobile technology will certainly keep the attention of those in the forefront of developments in the technological field. And the authors will continue to monitor bitcoin in its evolution.

But more importantly the movement in the field seems to be geared towards the promise that blockchain technology brings to the economic and financial realm. When layers of redundancy can be removed it augurs well for the speed of transactions in a fast-paced world. It is a development that needs to be monitored as well.

CONCLUSION

This update certainly enhances our knowledge and understanding of where bitcoin and blockchain technology are at this point in their evolution in the technology field.

Bitcoin no longer hogs the limelight today. Gone are the days when scandal and controversy seemed to plague it. The volatility has seemed to have settled and the focus of attention has been on the stability of this cryptocurrency as a medium of exchange and store of value little touched by the ravages of the market. Its underlying block chain technology is moving towards further uses that can help it find a niche in the world of technol-

ogy innovation. From a management perspective in whatever field - accounting, finance, law - the direction towards which things are moving not only in the bitcoin realm but in the blockchain field spells efficiency with the removal of redundant layers and the verification of transactions being undertaken in a split second. Such speed and efficiency are after all what the world of technology brings to people's daily lives. Such is the future promise of this type of technological development.

INTRODUCTION

The advent of the digital currency systems has revolutionized the concept of money transfer by allowing the internet based creation, storage and transference of money. In the past few years, the digital currency systems have emerged as an efficient means of money transfer. They have received worldwide adoption by providing a medium of exchange based on mathematical operations and by taking the currencies out of the control and manipulation of the governments. In addition to being used in the e-commerce and commercial sectors, the digital currencies have also attracted a large population of the earth which cannot get access to the formal banking systems. The crypto-currencies, being one of their types, involve different cryptographic functions for their creation and transference, in a trusted and secure environment. The use of crypto-currencies has progressed from a virtual concept to reality by the evolution of Bitcoin. The success of this concept has led to the creation of many other crypto-currencies which include Litecoin, PeerCoin, Namecoin, Quarkcoin, Primecoin and Zetacoin (Stevenson, 2013). Bitcoin, along with the other crypto-currency systems, is very popular in the business world and the global economy, due to its decentralized peer-to-peer architecture. In comparison with the other payment platforms, which maintain a private communication network for sending and receiving money, Bitcoin uses the internet as its medium of transference.

By Looking critically into the Bitcoin protocol, we can find some weaknesses that can be violated by the attackers for malicious purposes. In the past few years, a lot of vulnerabilities have been exploited causing the users to lose their bitcoins (L., n.d.), (Blasco, 2013), (arXiv, 2014). Matthew Wilson et al. (Yelowitz, 2014) analyze the characteristics of the Bitcoin users based on the Google search data and found that illegal activities and programming enthusiast are related to Bitcoin search but no correlation was found with political and investment motives. As of March 2014, bitcoins of worth 502,081,166.11\$ have been stolen (L., n.d.). Based on the empirical analysis of Bitcoin exchange risks, it is found that the failure rate of bitcoin exchanges is 40% (Christin, 2013). Mt. Gox that was considered to be the largest Bitcoin exchange, got bankrupt in February 2014, allegedly due to theft, resulting in the loss of 850,000 bitcoins, out of which 20,000 were later recovered (https://en.bitcoin.it/wiki/Mt._Gox, n.d.).

BACKGROUND

The Bitcoin¹ protocol was first introduced in 2009 by a pseudonymous developer Satoshi Nakamoto (Nakamoto, 2008). Since then, it has been widely adopted as a payment procedure for many e-commerce businesses as well as regular stores. This crypto-currency along with the others,

DOI: 10.4018/978-1-5225-2255-3.ch251

is considered to be a convenient way of achieving the open source peer-to-peer money. It operates in the cyberspace and requires Bitcoin wallets for storage purposes as well as for the generation of Bitcoin addresses. At the time of this writing, the Bitcoin market capitalization is \$5.8 billion (Crypto-Currency Market Capitalizations, n.d.). Keeping in view its frequent usage, Bitcoin ATMs have been deployed in various parts of the world to facilitate its users (Bitcoin ATM News, n.d.). In comparison with the Visa transactions, where the transaction speed is 2000 tps (transactions per second) and PayPal which has 115tps transaction speed, the Bitcoin network is restricted to 7 tps (Scalability, n.d.). In spite of these statistics, the advantages of Bitcoin transaction over other transaction mechanisms like PayPal, Western Union and M-Paisa etc. cannot be neglected. It gives the users the advantage of carrying out instant, anonymous and irrevocable transactions with very low transaction fees. The original Bitcoin paper (Nakamoto, 2008) presents a brief overview of the architecture and the protocol but a lot of details are missing in it. With the passage of time, a number of suitable changes and ideas have been suggested through the Bitcoin Improvement Proposals (BIPs) which are incorporated after being approved by the Bitcoin community.

In the last few years, researchers all over the world are working on Bitcoin security and there is still a need for a comprehensive assessment of attacks that are targeting the Bitcoin transactions. In this chapter, we investigate the Bitcoin protocol in detail. We have analyzed the Bitcoin architecture and its major components. We then review the Bitcoin protocol considering a use case scenario to demonstrate how a Bitcoin transaction takes place. The vulnerabilities and attacks section heuristically show how attacks like double spending, selfish mining, compromising anonymity and malware attacks can be carried out in the currently deployed versions of Bitcoin protocol. A comparison between different crypto-currencies with respect to their features and possible attacks is also presented.

BITCOIN ARCHITECTURE

In comparison with the traditional currencies that depend on a trust based model for their creation, circulation and transference, Bitcoin relies on a Proof-of-work (discussed in detail later in this chapter) based peer-to-peer model.

Being a crypto-currency, the Bitcoin protocol makes use of the hash functions and public key cryptography for the generation and transmission of bitcoins. A single bitcoin can be regarded as a series of digital signatures. For sending bitcoins to another entity, the sender digitally signs a hash of the involved previous transactions out of which the bitcoins are sent to the receiver as proof of possession of those bitcoins. The receiver can easily verify the series of digital signatures. Figure 1 shows the major components that constitute the Bitcoin Architecture.

The Bitcoin exchanges are not an inherent part of the Bitcoin protocol, however, they are one of the means for obtaining the bitcoins. The Bitcoin users can trade the bitcoins in exchange of the traditional or digital currency. Another way is to get bitcoins personally by asking the possessor of the bitcoins to transfer them to the buyer's Bitcoin wallet.

The Bitcoin users require Bitcoin wallets to carry out the transactions. Just like real life wallets, which are used to keep cash, Bitcoin wallets are also responsible of keeping record of the bitcoins sent and received by the owner. Bitcoin wallets generate a public/private key pair for carrying out a transaction.

The Bitcoin miners are the entities in the Bitcoin network that possess computational resources to compete in the mining process. Mining is the mechanism through which the transactions are recorded in the block chain. Mining involves a complex cryptographic mechanism known as Proof-of-Work (PoW). The motivation for the miners to perform mining is the Bitcoin reward that is granted to each miner. This reward is the source of creation of new bitcoins in the system. Initially, its value was 50 BTCs and is set in a way

Figure 1. Bitcoin architecture

that it is halved after every 4 years (Controlled Supply, n.d.).

Individual mining is tedious and the miner has to be efficient enough to be the first one to solve the PoW puzzle successfully. If an entity is not interested in mining individually, it can join a mining pool. Joining a mining pool increases the probability of a miner in solving the PoW as the miners are assigned smaller cryptographic puzzles to solve and are able to combine their computational power with that of others in the mining pool.

In addition to the reward, the miners also receive a very small amount of bitcoins as the transaction fees. If a transaction is processed in a way that it draws bitcoins from many addresses, then greater transaction fees is associated with it due to the large transaction size. When a miner successfully generates a block, the information

related to all of the transactions is incorporated in it and that miner can obtain the transaction fees.

The Block chain serves as a global ledger for keeping a record of all the confirmed transactions that have taken place since the first ever Bitcoin transaction.

BITCOIN PROTOCOL

The Bitcoin wallets generate a public/private key pair for carrying out a transaction. The hash of the public key is referred to as Bitcoin address which can be used to send or receive transactions. The Private Key is used to digitally sign the transaction in order to add sender's identity. All the transactions are signed and verified using the elliptic curve digital signature algorithm ECDSA. In such signature algorithms, public

key is derived by the multiplication of the base point of the elliptic curve with the private key. The elliptic curve used in Bitcoin is secp256k1 which is recommended in SEC 2 (Standards for efficient cryptography) (Research, 2000). Besides having the knowledge of the public key and the base point, it is not possible for anyone to derive the private key. This factor adds to the security of ECDSA. The ECDSA signatures also require a random parameter for each separate transaction made with the same private key.

Figure 2 explains how the Bitcoin transactions are digitally signed. A Bitcoin transaction comprises of two parts: input and output. Each part embeds certain scripts which control the future spending of the bitcoins that are being sent. The input of a transaction connects to a previous output. The Input consists of hashes of the previous transactions that client had with other users in the network. Amount of the current transaction is assigned out of these transactions. The purpose of taking hashes is to reference the output of the transactions from which this transaction is funded. It also comprises of a script called *scriptSig* which refers to the number of arguments that are expected by a script. The output consists of the amount to be sent to the receiver signed by the receiver's public key and the change to be sent back to the sender. A short script called *scriptPubKey* is also a part of the output which specifies the conditions under which the output could be redeemed. The script contains the hash of the ECDSA public key and a signature validation routine. For a valid transaction, the output script should evaluate to be true given the *scriptSig* provided in the input.

Each transaction is identified by a unique transaction ID which is the SHA-256 hash of the entire transaction.

Proof of Work

Bitcoin transactions are verified through the Proof-of-work which is used as a countermeasure for double spending attacks (discussed in the next section). The receiver of the transaction

Figure 2. Digital signatures in Bitcoin transactions

requires confirmation in the form of a proof from the majority of the nodes, that the amount is not double spent. This proof is provided using the PoW system which is based on the idea of Adam Back's Hashcash (Back, 2002). Hashcash ensures that the requester has spent considerable amount of CPU resources before receiving the services.

Bitcoin mining involves finding the PoW, in which a nonce is calculated by the miners using a random number generator (RNG) algorithm ran at a colossal rate. The nonce is calculated corresponding to an automatically generated challenge/difficulty. The block including the nonce when hashed under SHA 256, generate a string whose initial bits are consecutive zeroes (as specified in the challenge). The hash of the block (including the nonce) should satisfy the challenge/difficulty. The computational resources required for doing the PoW are directly proportional to the number of required zeroes. The first miner whose RNG spits out the correct nonce is the miner who gets the reward for solving the PoW. Any node of the Bitcoin network can become a miner if it possesses reasonable computing resources.

Once the PoW is solved, the block is broadcast to the network. The block will be accepted by the nodes only if the transactions are valid and are not double spent. Broadcasting the block also informs the other Bitcoin miners to quit mining this block and start working on another one. The verified block is then appended to the block chain. Each block is a reference to the previous one and results in formation of a continuous chain which serves as public ledger.

The average time for mining is about 10 minutes. Therefore, the memory pool of each node will contain all the unlogged transactions that have taken during the time period of these 10 minutes. For every 2016 blocks that have been mined, the network checks the performance of the miners. If it is greater than normal, the difficulty level of the PoW is increased. The difficulty in solving this cryptographic puzzle provides security as it ensures that no malicious entity can flood the block chain with conflicting blocks.

Suppose a merchant running an online business accepts bitcoins payments. In order to receive the payments, Bitcoin address of the merchant should be known to all of the customers. Practically, it is quite inefficient to have a separate transaction for each bitcoin transfer, considering the small size of such transactions. In this regard, Bitcoin protocol allows splitting and combining of transactions. Generally, there can be one input if previous transaction is large enough for the amount to be sent. If the previous transactions are small and amount to be sent is large, then there will be multiple inputs combining previous smaller transactions. Figure 3 explains a scenario of a Bitcoin transaction in which an entity **A** wants to send 50 bitcoins to entity **B**. **A** has received 20 BTCs from **C**, 25 BTCs from **D** and 10 BTCs from **E**. As discussed earlier, input part of the transaction contains hashes of the previous transactions which is digitally signed with private key of **A** ($P R_A$). Output contains the amount which is to be sent to **B** and the change amount that is to be sent back to **A**. In order to ensure that the desired amount is only received by **B**, the amount is encrypted using public key of **B** ($P U_B$). The change amount is encrypted using public key of **A** ($P U_A$).

For the validation of a transaction following steps take place:

1. Each node gets the transaction that was broadcast by the sender.
2. Each node checks the formatting of the transaction and confirms if the transaction is already present in the block chain. The

Figure 3. An entity **A** wants to send 50 BTCs to another entity **B**. Previously, **A** has received 20 BTCs from **C**, 25 BTCs from **D** and 10 BTCs from **E**.

unlogged transactions are temporarily stored in memory pools (memory buffers) of each node.

3. The miners compete in the formation of a block by participating in the mining process. PoW puzzle is calculated which involves a distributed time stamping mechanism to prevent double spending. This work requires a lot of computational power and hence miners are rewarded with a small percentage of transaction fee. If the nonce that solves the PoW is successfully found, then all the transactions in the memory pool are transferred to the block, which is then broadcast. The purpose of the broadcast is to tell other nodes to start working on a new block.
4. The nodes validate the block by confirming the PoW and it is added to the block chain. The miners work on the construction of new blocks.

Conflict Resolution and Consensus

If two miners succeed in finding the PoW simultaneously, then after broadcasting, some of the nodes will receive one of the blocks whereas others will receive the other one. This results in the formation of a fork as shown in fig 4. The nodes with the first block will work on it and keep a copy of the second one. Similarly, the nodes that receive the second block first will mine further blocks on this block and keep a copy of the first block. The conflict will be solved after a new PoW is found and one branch becomes longer than the other one. In such case, the blocks in the shorter branch will

Figure 4. Forks in block chain

be discarded and the miners will shift to working on the longer one. The discarded blocks are called orphan blocks.

VULNERABILITIES AND POSSIBLE ATTACKS

Despite being an efficient and convenient way of electronic funds transfer, the Bitcoin transactions are becoming a target of many known and zero day attacks. No holistic solution has been proposed up till now to cater these attacks. This leads to the need of certain modifications in the protocol by

the consent of the Bitcoin community. Figure 5 illustrates the vulnerabilities particular to the main entities in the Bitcoin architecture. The flow starts from a sender who has installed a Bitcoin wallet on his system in order to send some bitcoins to the receiver. The sender's bitcoin wallet is prone to malware attacks and theft which can result in the loss of private keys generated by the wallet. The sender can trick the receiver by double spending the amount of bitcoins he is going to send to the receiver. Hence, the sender can deprive the receiver from the sent bitcoins and can reuse those bitcoins. Malicious mining is a major threat in Bitcoin transactions. If malicious miners have a

Figure 5. Vulnerabilities in Bitcoin architecture

large hash rate, then they can easily add conflicting transactions in block chain and can steal bitcoins. Bitcoin transactions which were initially claimed to be completely anonymous, can reveal the identity of the communicating ends. In order to buy bitcoins from exchanges, bitcoin users have to provide some personal information. This personal information can be revealed through man in the middle attack and malicious exchanges. Figure 5 shows some of the attacks that are possible in Bitcoin transactions.

Double Spending Attacks

While a transaction is taking place, there is a possibility that the sender is sending the same bitcoins to two receivers at a time. This leads to a problem known as double spending. Double spending attacks occur when a user assigns same amount of bitcoins (BTCs) to more than one user at a time, allowing users to spend the same amount of bitcoins twice. One of the possibilities of double spending is that the attacker tricks the vendor by sending him a transaction which actually cannot be redeemed. In order to avoid detection, attacker has to replace the transaction as well as the block in the block chain which contains that transaction. This requires a lot of computational power due to the re-computation of that block as well as all subsequent blocks in the block chain.

The Bitcoin system uses hash based PoW schemes to protect against the double spending attacks, but the attackers have found ways to bypass such schemes.

The chances of a double spending attack being successful depend on the attacker's hash rate (<https://en.bitcoin.it/wiki/Double-spending>, n.d.). If an attacker can control more than half of the network's hash rate, then this attack is called 51% attack. In this attack, the attacker makes a transaction to the vendor and meanwhile keeps on mining conflicting block in which a double spending transaction is included. In the presence of some conflicting transactions, the miners have to vote for the valid block by appending further

blocks to the block the miners think is valid. The longest block chain is accepted whereas the other one is discarded. The attacker can get the false blocks verified by the network, by generating blocks in order to keep the chain longer than that of the legitimate peers (Drainville, 2012). After receiving the BTCs, the vendor waits for some confirmations and then provides the service. Once the service is provided, the attacker releases the fork by overtaking the number of blocks on the legitimate chain. Figure 4 highlights two conflicting blocks resulting in the formation of a transaction fork.

Selfish Mining

Mostly, the Bitcoin miners work in the form of groups called mining pools and share the revenue according to their computational power. This honest mining process is the backbone of Bitcoin protocol. A lot of research has been done to analyze the behavior of bitcoin miners. According to the researchers, Ittay Eyal et al. (Siler, 2013), Bitcoin mining is no longer incentive compatible. A large number of selfish miners can join a mining pool and get their mining reward larger than their fair share.

In this attack, if the selfish miners find a block 'X', they do not reveal it to the network, keeping it secret. All the other miners keep on finding that block, as without discovering it, they cannot move to the next block 'Y'. In the meantime, the selfish miners start working on next blocks ('Y', 'Z' etc.). When the honest miners find block 'X' and distribute it to the network, the selfish miners immediately release all the work they have done so far, which might be several blocks (i.e. 'X->Y->Z...'). As the revenue goes to the miner of longer chain, selfish miners win over the honest miners and get the incentive (Arvind Narayan, 2013).

The revenue that the selfish miners get increases super-linearly with the size of the group. So, the colluding miners usually try to add more miners into their group to increase their cumulative computational power. This snowball scenario

helps them to avoid the situation in which the honest miners find the block before the selfish miners would find the second block, due to enhanced computational resources.

Anonymity

Initially, when the Bitcoin protocol was designed, it was claimed that the protocol provides complete anonymity of both the sender and the receiver and they cannot be traced back. But recently, the researchers have found ways to identify the sender and the receiver by using some extra computational power. The Bitcoin community itself states that the current implementation is not very anonymous (Anonymity, n.d.). The Bitcoin protocol is now considered to be pseudo-anonymous.

Each Bitcoin transaction has a list of inputs and outputs. The input contains previous transactions so that the miners would verify that the bitcoins are not already spent (to avoid double spending). The transactions usually have two outputs; one output belongs to the receiver while the other output contains address of sender, to return the extra bitcoins. Using the reference to previous transactions from the input, transaction graphs can be built. These graphs can help in tracking the sender (Moser, 2013).

People usually have to provide their personal information such as, copy of National ID card etc., to bitcoin exchanges, in order to buy bitcoins. Also, the transactions are stored publically in the block chain, so anyone can analyze these transactions to find the links between the previous owners of bitcoins.

Malware Attacks

The cyber-criminals use malicious software to attack systems that have installed the Bitcoin wallets. In most cases, the purpose is to steal critical information. They try to expand the attack by targeting more and more machines, creating a botnet.

The Bitcoin wallets are the digital place to store the private keys used to access bitcoins. If the keys are compromised, all of the bitcoins are lost. To attack the bitcoin wallets, the attacker

writes some malicious code and spreads it to the botnet. The malware steals data from the wallet.dat file which contains sensitive information related to the keys and user preferences. Therefore, it is a common security practice to encrypt this file. However, it has been identified that some of the recent malware detected have key logging capability which lets them steal the password to decrypt the required file. Khelios and IRC are some known malwares that do this job for the attackers (Blasco, 2013). MtGox, allegedly got bankrupt due to this attack. It lost 850,000 bitcoins, out of which, 750,000 bitcoins belonged to customers (arXiv, 2014).

Apart from attacking the Bitcoin wallets, some malware are designed to attack the computational resources of different machines. The incentive driven mining process motivates the miners to increase their computational power in order to get more and more reward. The attackers have now found a way to win the competition. They write and install Bitcoin daemons on victims' machine and connect it to the mining pool. The attacker then uses victims' computational power to mine bitcoins. As, the computational power is enhanced, the chances of solving the PoW increase, resulting in increase in miners' incentive. Such malware is spread through fake emails, Skype, and phishing websites. Some of the known malware are Zeus, Dorkbot and Ufasoft (Blasco, 2013).

COMPARISON WITH OTHER CRYPTO-CURRENCIES

Bitcoin became the pioneer crypto-currency by introducing the concept of decentralized peer-to-peer cryptography based digital currency. The idea of Bitcoin has paved the way for the creation of many other crypto-currencies which have been collectively termed as the 'altcoins'. The altcoins are considered to be modified and improvised versions of Bitcoin but still lag behind in terms of acceptance, market capitalization and liquidity. Table 1 highlights distinguishing features of Bitcoin along with top three altcoins with respect to market capitalization.

Table 1. Table showing salient features of Bitcoin and other crypto-currencies

Crypto-Currency	Features				Advantages	Disadvantages
	Hashing Algorithm	Mining Process	Current Mining Reward	Maximum Supply		
Bitcoin (https://en.bitcoin.it/wiki/Main_Page , n.d.)	SHA 256	Proof-of-work	25 coins (halves after every 210,000 coins)	21million	• Greatest market capitalization among crypto-currencies. • Widely accepted by businesses.	• Requires extensive computational resources (ASICs) for mining (in comparison with Litecoin, CPU mining is not possible in Bitcoin) • Prone to various attacks. (51% attack, selfish mining, compromising anonymity).
Litecoin (Litecoin-Open Source P2P Digital Currency, n.d.)	SCRYPT*	Proof-of-work	50 coins (halves after every 840,000 coins)	84million	• Greatest market capitalization among altcoins. • Faster transaction confirmation. • Higher transaction volume in the blockchain. • Market entry costs are very low which allow anyone with a computer and internet to mine litecoins.	• Lesser market acceptance. • Exposed to similar attacks as of bitcoin (51% attack, selfish mining, and compromising anonymity).
Peercoin (http://peercoin.net)	SHA 256	Proof-of-work + Proof-of-Stake **	25 coins (halves after 16 times increase in the network) but as the reward decreases, reward will be proportional to the miner's stake in the currency.	No limit (designed to reach an annual 1% inflation rate)	• No limit on maximum supply. • Lesser chances of 51% attack/monopoly or due to proof-of-stake system (as new coins are generated based on the holding of the individual.) • Energy efficiency (lesser power consumption required for proof-of-stake as compared to proof-of-work that involves resource intensive hashing functions).	• Lesser market acceptance. • Rich get richer. • People get rewarded for hoarding peercoins.
Namecoin (http://www.econinfosec.org)	SHA 256	Proof-of-work	25 coins (halves after every 210,000 coins)	21million	• Same implementation as Bitcoin. • Can be used for money transfer as well as for storing information (DNS or identification/authorization) in the blockchain. • Provides decentralized DNS to prevent internet censorship.	• Lesser market acceptance. • Users have to pay for network fees along with transaction fees. • Prone to attacks like 51% attack and compromising anonymity.

* SCRYPT is slightly simpler algorithm as compared to SHA 256 which is less susceptible to ASICs (Application Specific Integration Circuits) designed for Bitcoin mining. (<http://citeseerx.ist.psu.edu>). It is designed to make mining accessible to everyone without the requirement of computational resources. (Script.CC, n.d.)

** A hybrid of proof-of-work and proof-of-stake is used by Peerecoin in the mining process. According to the design, proof-of-work is used only in the initial generation of coins, but in the long term proof-of-stake would be used. Proof-of-stake reduces the chances of 51% attack by allowing coin generation based on miner's holding in the network. (<http://peercoin.net>)

Based on the features of each of the crypto-currencies, table 2 illustrates a list of crypto-currencies along with the possibilities of different attacks associated with them. The tick mark ✓ indicates the existence of a particular attack, whereas cross mark × indicates its absence. As discussed in section IV, Bitcoin is prone to attacks like double spending, selfish mining, compromising anonymity and malware attacks etc. Altcoins are designed either to provide additional functionalities on the top of the Bitcoin protocol or to fix the issues found in the protocol. Litecoin transactions have faster block generation rate and provide greater resilience to double spending attacks. As a security measure against double spending attacks, it is a standard practice for a merchant to wait for a sufficient number of blocks/confirmations to be added to its transaction's block. Litecoins transactions can have more confirmations during the same time that is used with Bitcoin, therefore the probability of double spending attacks is lesser. Transactions in Litecoin, Peercoin and Namecoin are all pseudo-anonymous like Bitcoin. Malware attacks can be observed in all crypto-currencies and can be avoided by adopting efficient end user security practices. Peercoin prevents 51% attacks through proof-of-stake scheme which allows miners to generate coins based on their share in the network. A successful double spending attack would require an attacker to possess a very large number of coins, which is practically infeasible. Peercoin prevents selfish mining by providing a fair distribution of coins scheme through proof-of-stake.

FUTURE DIRECTIONS

Digital currencies like Bitcoin are of growing interest to economists, cyber security experts, speculators and media. Never in history have people experienced a decentralized money transfer system that offered anonymous and unregulated transactions to be carried out with very less transaction fees. World's unbanked population finds no choice other than Bitcoin for sending money to other people in the world. On a larger scale, the worldwide national adoption of decentralized and virtual currencies will result in economic neutrality and political transparency.

It cannot be said with surety that Bitcoin or any other crypto-currency will be able to replace the real currency but there is a great desire for the digital currencies. Human beings are considered to be the weakest link in the security chain, therefore there is a dire need of a decentralized and trustless system as it is better to trust on mathematical operations than humans. A large number of credible researchers and entrepreneurs are investing their time and money in this domain. The advantages that digital currency systems provide over physical monetary systems cannot be overlooked. However, certain economic and security challenges act as a hurdle in world-wide adoption of virtual currencies. In order to ensure successful and world-wide adoption in future, security weaknesses in the protocol need to be dealt with. Moreover, price fluctuations are causing inconvenience for businesses accepting bitcoins as they have to adjust their prices accordingly.

Table 2. Crypto-currencies and their possible attacks

Crypto-Currency	Attacks			
	Double Spending	Selfish Mining	Compromising Anonymity	Malware Attacks
Bitcoin	✓	✓	✓	✓
Litecoin	×	✓	✓	✓
Peercoin	×	×	✓	✓
Namecoin	✓	✓	✓	✓

In short, Bitcoin is evolving with progress in economic and technological conditions and its future is quite vague. If the Bitcoin community puts its efforts in resolving the inherent security issues in its protocol, then Bitcoin surely has the capability of being a strong competitor of real currency.

CONCLUSION

In this chapter, we have studied the Bitcoin protocol from a critical perspective and have highlighted various vulnerabilities that need to be addressed. We have presented a holistic survey of attacks that can take place during the Bitcoin transactions. We also discuss a comparative analysis of Bitcoin and other crypto-currencies by highlighting their specific features, advantages and disadvantages and possible attacks. Based on our analysis, it is suggested that changes need to be made to the Bitcoin protocol by the consensus of the open source community in order to overcome the weaknesses.

KEY TERMS AND DEFINITIONS

Altcoins: All the crypto-currencies other than the Bitcoin.

Crypto-Currencies: The type of digital currencies that use cryptography for their creation, security and transference.

Digital Currencies: The currencies that use internet for their transference.

Digital Signature: A mathematical scheme for ensuring the authenticity of a message. The sender encrypts the message using its private key in order to create a digital signature. By doing this, the sender adds his identity to the message since the private key is only owned by that particular sender.

Proof-of-Work: A defense mechanism against Denial of Service attacks in which the service requester has to perform some mathematical task before accessing the services.

Public Key Cryptography: An encryption technique in which each entity possesses a key pair (public/private key). In comparison with symmetric encryption in which single key is shared among the sender and the receiver, the public key cryptography involves two keys without the need of sharing them.

ENDNOTE

- ¹ The term bitcoin will be used in two contexts throughout the paper. Bitcoin (with 'B' in capitals) refers to the protocol suggested by Satoshi Nakamoto whereas bitcoin refers to the currency or the amount (often abbreviated as BTCs).

INTRODUCTION

Throughout the World Internet users, buyers and businesses are growing at an exuberant speed. Prevalence of computers and internet as one of the most influential technologies and its integration with business has made sale of goods and services through websites a profitable and low cost affair (Doostar, Akbari, & Abbasi, 2013). Businesses have realized that they can use internet as a powerful tool to increase overall service offerings (Griffith & Palmer, 1999). On the other hand, customers can avail benefit like convenience, availability of wide variety of product/service, competitive prices, extensive information, comparing alternatives etc. However, most of the retailers are selling similar products and gaining competitive advantages solely based on a cost leadership strategy is difficult (Jun, Yang, & Kim, 2004; Shankar, Smith, & Rangaswamy, 2003). In this scenario, researchers have pointed out that superior service quality can be critical for Internet retailers' long-term success (Fassnacht & Koese, 2006; Zeithaml, Parasuraman, & Malhotra, 2002). However, perception of the service quality can significantly differ between different customers, leading to difference in their satisfaction and future behavior (Sánchez-Pérez, Sánchez-Fernández, Marín-Carrillo, & Gázquez-Abad, 2007). Many

researchers have highlighted how demographic factors can influence customers' preference of online store visit (Phang, Kankanhalli, Ramakrishnan, & Raman, 2010), information search behavior (Kalia, Singh, & Kaur, 2016), consumer's online buying behavior (Li, Kuo, & Russell, 1999), differentiation of web-shoppers and non-shoppers (Karayanni, 2003) and evaluation of the e-service quality (Barrera, García, & Moreno, 2014). Ganesan-Lim, Russell-Bennett, & Dagger (2008) also mentioned in their literature review that individual consumers perceive service differently therefore quality perceptions may vary from one segment of the population to another. Acknowledging the fact that demographic information is essential for segmentation and targeting (McCarty & Shrum, 1993) or relevant in formulation of marketing or product strategy by internet retailers (Chang & Samuel, 2006), this study tries to understand whether significant difference in perceived service quality (PSQ) exist within demographic characteristics of online shoppers, such as education, age, gender, monthly income, occupation and marital status. This article is organized as follows: a literature review relevant to service quality and demographic effects on service quality perceptions is done to develop hypotheses. Then methodology and results are discussed. At the end conclusion and managerial implications are drawn.

BACKGROUND

Online Service Quality

To measure customer perceptions of service quality in service and retailing organizations Parasuraman, Zeithaml, & Berry (1988) developed a 22-item survey research instrument called SERVQUAL. Later, through focus group research with online shoppers, Zeithaml, Parasuraman, & Malhotra (2000) developed a framework for consumer evaluation of electronic service quality, known as e-SERVQUAL. They defined e-service quality (e-SQ) as, “the extent to which a website facilitates efficient and effective shopping, purchasing, and delivery” (Zeithaml et al., 2000). Their framework considered 11 dimensions of e-SQ i.e. access, ease of navigation, efficiency, flexibility, reliability, personalization, security/privacy, responsiveness, assurance/trust, site aesthetics, and price knowledge. On the basis of SERVQUAL number of scales for measuring online service quality were developed in subsequent years; for example, WebQual 1.0 (S. Barnes & Vidgen, 2000), PIRQUAL (J. Francis & White, 2002), WebQual 4.0 (Barnes & Vidgen, 2003), E-S-QUAL and e-RecS-Qual (Parasuraman, Zeithaml, & Malhotra, 2005), E-A-S-QUAL (M. Kim, Kim, & Lennon, 2006), eTransQual (Bauer, Falk, & Hammerschmidt, 2006) and eSELFQUAL (Ding, Hu, & Sheng, 2011). There was origin of some independent scales like SITEQUAL (Yoo & Donthu, 2001), WebQual (Loiacono, Watson, & Goodhue, 2002), IRSQ (Janda, Trocchia, & Gwinner, 2002), .comQ (Wolfinbarger & Gilly, 2002) and eTailQ (Wolfinbarger & Gilly, 2003). Number of researchers have highlighted why consumer perception of online service quality is important (Cai & Jun, 2003; Cheng, Wang, Lin, Chen, & Huang, 2008; J. E. Francis & White, 2002; Gounaris, Dimitriadis, & Stathakopoulos, 2005; Janda et al., 2002; Jun et al., 2004; Lee & Lin, 2005; Yang & Jun, 2002; Yoo & Donthu, 2001) and how service quality can significantly affect attributes like, loyalty (Dai, Haried, & Salam, 2011; Ding et al., 2011; J. Kim, Jin, & Swin-

ney, 2009; Srinivasan, Anderson, & Ponnnavolu, 2002; Swaid & Wigand, 2009; Wolfinbarger & Gilly, 2003; Zehir, Sehitoglu, Narcikara, & Zehir, 2014), satisfaction (Bauer et al., 2006; Cho & Park, 2001; Ding et al., 2011; J. Kim et al., 2009; S. Kim & Stoel, 2004; Szymanski & Hise, 2000; Wolfinbarger & Gilly, 2003; Yang, Peterson, & Cai, 2003), customer retention (Wolfinbarger & Gilly, 2003), perceived value (Bauer et al., 2006; Zehir et al., 2014), attitude toward the website (Wolfinbarger & Gilly, 2003), behavioral intentions (Collier & Bienstock, 2006), and service enjoyment and commitment (Dai et al., 2011).

Demographics and Service Quality

Different motivations drive shoppers to react differentially to diverse marketing messages (Moe, 2003). For instance, shoppers may search for product information actively or casually browse a webstore. This difference can be ascribed with customer's demographics and these variables offer valuable insights into ‘who consumers are’ and ‘what they need’ (Kalia, 2016a; Phang et al., 2010). For segmentation and targeting, researchers consider demographic information fundamentally necessary (McCarty & Shrum, 1993) and suggested to understand the affect of demographics like age, income and gender with respect to customer perceptions of quality (Lim et al., 2008). This section reviews prior research on the impact of demographics on service quality perceptions. As compared to previous studies, where two, three or maximum four demographic variables are undertaken; this study has comprehensively considered six demographic variables i.e. education, age, income, occupation, marital status and gender.

Education

Researchers observed that education level influence the evaluation of service quality (Min & Khoon, 2013). Vrechopoulos et al. (2001) discovered that Internet shoppers are mostly University graduates and postgraduates, simi-

larly Kalia (2016) reviewed that online shoppers are well educated and less resistant to change, more open-minded, venturesome, cosmopolitan in outlook, socially mobile, self-confident and mature. Barrera et al. (2014) highlighted that people without a university degree score perceived quality service higher than people with a university degree. Kumbhar (2011) argued that on the basis of education level perceived service quality, perceived value from e-banking service and overall satisfaction in e-banking vary among customers. Collectively, the preceding discussion leads to the following hypothesis.

H1: *Perceived service quality in online retail differ according to education.*

Age

Consumer age affects service quality perceptions (Lim et al., 2008). Reason to shop online vary in Internet shoppers according to their age, for example middle-aged customers (24-44) primarily shop online for 'convenience' than 'price' and 'product selection' (Chang & Samuel, 2006). On the other hand, older shoppers are more likely to prefer search/deliberation over hedonic browsing than younger shoppers (Phang et al., 2010). Pretorius and Smit (2010) observed difference in overall website satisfaction across the age groups and concluded that younger individuals, on average, are more satisfied with websites. Similarly, Barrera et al. (2014) found that people under 24 years perceive a greater service quality than those over 24 years. Few other studies also confirmed that internet shoppers are young and fall within the age bracket of 21-30 years (Kalia, 2016a) or 25-44 years (Vrechopoulos et al., 2001). Khare (2011) observed that Indian customers' perceptions towards the service quality of multinational banks differ across age categories, Kumbhar (2011) noticed that (Khare, 2011) perceived service quality, perceived value from e-banking service and overall satisfaction in e-banking differ with age group of the customer and Butler et

al. (1996) observed that age adequately predict one component of perceived hospital quality. In sum, the above discussion leads to the following hypothesis.

H2: *Perceived service quality in online retail differ according to age.*

Income

Internet shoppers who are motivated to purchase online vary in income. Middle-incomes (Aus\$40,000 to \$69,999) tend to be primarily influenced to purchase online for the reason of 'convenience' relative to 'price' and 'product selection' (Chang & Samuel, 2006). Kumbhar (2011) observed difference in perceived service quality, perceived value from e-banking service and overall satisfaction in e-banking due to varying income level of the customers. At large, online shoppers have higher or above average household/disposable income incomes (Kalia, 2016a). Vrechopoulos et al. (2001) also found that internet shoppers have average monthly household income of 300000-2000000 GRD. Above discussion lead to following hypothesis.

H3: *Perceived service quality in online retail differ according to income*

Occupation

Past studies have affirmed that perceived service quality, perceived value from e-banking service and overall satisfaction in e-banking differ by profession of the customers (Kumbhar, 2011). Vrechopoulos et al. (2001) discovered that Internet shoppers are largely scientists, private employees or freelancers. Kalia (2016) also reviewed that majority of online shoppers are wealthy or dual-career families with small children. Following hypothesis is proposed in the light of above discussion.

H4: *Perceived service quality in online retail differ according to occupation*

Marital Status

Marital status has been found to moderate the relationship between usefulness, enjoyment, external characteristics and reliability (Doostar et al., 2013) and Internet shoppers are mostly single (Vrechopoulos et al., 2001). Bhatnagar, Misra, & Rao (2000) concluded that marital status had no significant effect, except hardware category where marital status did have a significant effect. Majority of studies supported the fact that:

H5: *Perceived service quality in online retail differ according to marital status.*

Gender

Researchers have found that gender is influential in the evaluation of service quality (Min & Khoon, 2013) and Internet shoppers who are motivated to purchase online vary in gender or gender adequately predict components of perceived quality (Butler et al., 1996). Certain studies observed that women have a higher valuation of the service quality of Web sites than men (Barrera et al., 2014) and primarily, female are influenced to purchase online for the reason of 'convenience' relative to 'price' and 'product selection' (Chang & Samuel, 2006). Females also express greater overall website satisfaction (Pretorius & Smit, 2010). There have been studies which confirmed that gender moderates the relationship between usefulness, enjoyment, external characteristics and reliability (Doostar et al., 2013). Certain studies found that Internet buyers tend to be male than females, because women perceive a higher level of risk and engage in high exploratory behavior while buying online than men (Kalia, 2016a; Vrechopoulos et al., 2001). Khare (2011) found that Indian customers' perceptions towards the service quality of multinational banks differ between the two genders. On the basis of above literature review following hypothesis is proposed.

H6: *Perceived service quality in online retail differ according to gender.*

E

METHODOLOGY

Under methodology, research goal, sample and data collection are talked about. Subsequently, results of Kruskal-Wallis (H Test) to check significant difference in perceived service quality in online retail with respect to different demographic factors have been discussed. At the end results of post hoc test have been shared.

RESEARCH GOAL

There have been previous studies which have partially discussed demographics and service quality but there is shortage of studies which comprehensively and directly discuss the impact of demographics on perceived service quality in online retail. Further, this study is conducted in India, which is one of the most promising e-commerce market in Asia-Pacific region (eMarketer, 2015). India's online retail industry is estimated to grow to healthy 50-55 percent CAGR of Rs 504 billion by 2015-16; this indicates that Indian e-retail market has huge potential for future growth. However, due to sudden boom, competition in e-commerce market in India is getting intense (Kalia, 2016c); so much that e-retailers in India are adapting their business model to sustain and win (Kalia, 2015). Under such conditions, this research tries to determining the impact of demographics (education, age, income, occupation, marital status and gender) on perceived service quality in online retail.

SAMPLE AND DATA COLLECTION

An online survey was developed to test the hypothesis. Mail containing link to questionnaire was sent to respondents in three capital cities of

Northern India i.e. Chandigarh, Delhi/National Capital Region and Jaipur. Selection of these cities was based on eBay.in Census 2012 which identified these cities among top ten e-commerce hubs (Ebay.in, 2012). Hence, it was appropriate to collect data from respondents from these cities, who have made atleast one online purchase in past six months from popular e-retailers of India and gone through real experience of an online purchase. Snowball sampling (Malhotra, 2007) was deployed i.e. an initial group of respondents were selected randomly and subsequent respondents were selected based on the referrals. Considering 300 cases as good sample size (Comrey & Lee, 1992; Tabacnik & Fidell, 1996; Vanvoorhis & Morgan, 2007), total 308 responses have been used for data analysis. E-retailers in this research denotes business-to-consumer e-commerce companies selling products to consumers in categories like clothing & accessories, books & magazines, mobile phones & accessories, auto accessories & parts, memory cards, pen drives & HDD, watches, laptops & computer peripherals, shoes & other footwear, movies & music (CD/DVD) and home appliances. Scale developed by Jun et al. (2004), consisting twenty-one items to measure perceived online retail service quality has been used. Demographic profile of the respondents has been depicted in Table 1.

SCALE RELIABILITY AND CONSTRUCT VALIDITY

Cronbach's Alpha value of 0.928 confirmed the reliability of 21 item scale. KMO score of 0.926 (Kaiser & Rice, 1974) and Bartlett's Test score under 0.001 (significant) indicated that data is suitable for factor analysis. Items were checked for their communality scores and all the items scored greater than permissible limit i.e. <.30. Four factors accounted for 59.2 percent of the total variance. To examine the dimensions principal component factor analysis with varimax rotation was used. For purification of items many

researchers used 0.5 cut-off for loading scores and deleted items with primary factor loadings less than 0.5 (Cai & Jun, 2003; J. E. Francis & White, 2002; Jun et al., 2004; Long & McMellon, 2004). On similar lines primary factor loadings less than 0.5 were filtered out and total nineteen items were retained out of initial twenty-one items. Since all items have a factor loading greater than 0.5, therefore its confirmed that constructs are "unidimensional and factor distinct, and the items used to operationalize the constructs are all loaded onto a single factor" (Chong, 2013). Four factors were derived i.e. ease of use/attentiveness, access, reliable/prompt response and credibility/security. Cronbach's alpha reliability analysis results for these four factors extracted were 0.80,

Table 1. Demographic findings (n = 308)

Demographic Variables		n	%
City	Delhi/NCR	108	35.1
	Jaipur	93	30.2
	Chandigarh/Tricity	107	34.7
Education	Under Graduate	52	16.9
	Graduate	82	26.6
	Postgraduate	109	35.4
	Professional	65	21.1
Age	18-24 Years	137	44.5
	25-31 Years	127	41.2
	32-38 Years	32	10.4
	39 Years & Above	12	3.9
Gender	Male	168	54.5
	Female	140	45.5
Monthly Income	Less than 50,000	66	21.4
	50,001-80,000	72	23.4
	80,001-1,10,000	34	11.0
	1,10,001- 1,40,000	28	9.1
	More than 1,40,000	108	35.1
Profession	Business	28	9.1
	Service	173	56.2
	Student	107	34.7
Marital Status	Married	72	23.4
	Unmarried	236	76.6

0.82, 0.81 and 0.75 respectively. Cronbach α coefficient scores mentioned above indicated good reliability (Table 2).

ANALYSIS AND RESULTS

Kolmogorov-Smirnov one sample test revealed that the data needs application of non-parametric tests. Therefore, data has been analyzed by deploying Mann-Whitney U Test and Kruskal-Wallis H test (Table 3 and Table 4).

It was observed that no significant difference exists in perceived service quality in online retail with respect to education. Therefore, hypotheses H1 is rejected. The result is coherent with findings of Ilias et al. (2009) they found no difference in students' satisfaction towards service quality determinants and overall service quality on the basis of semester of studies and Phang et al. (2010), they reported that no significant difference exist between the shoppers adopting a search/deliberation strategy and those adopting a hedonic browsing strategy within different education groups.

No significant difference was found in perceived service quality in online retail with respect to age in this study. Therefore, hypotheses H2 is rejected. This finding is consistent with the results of Doostar et al. (2013), they discovered that age don't moderates the relationship between usefulness, enjoyment, external characteristics and reliability and Min and Khoon (2013), they discovered that age factor does not make any significant difference in the key elements of the service quality evaluation.

No significant difference was observed in perceived service quality in online retail with respect to income in this study. Therefore, hypotheses H3 is rejected. This result is coherent with findings of Ganesan-Lim et al., (2008) i.e. they noticed no differences in service quality perceptions on the basis of income. Phang et al. (2010) also concluded that no significant difference exist between the shoppers adopting a search/deliberation strategy and those adopting a hedonic browsing strategy within different income groups.

However, Kruskal-Wallis (H Test) values indicated that significant difference exist within occupational categories with respect to perceived service quality dimensions of "access" ($H(2) = 7.066, p = 0.029$) and "credibility/security" ($H(2) = 7.247, p = 0.027$). Hence, H4 has been accepted.

No significant difference was observed in perceived service quality in online retail with respect to marital status in this study. Therefore, hypotheses H5 is rejected. This result is similar to the conclusions of Kalia (2016) who profiled online shoppers and suggested that marital status has no significant effect.

It was observed that no significant difference exists in perceived service quality in online retail with respect to gender. Therefore, hypotheses H6 is rejected. There have been studies which support above finding, for example Ganesan-Lim et al. (2008) found no differences in service quality perceptions on the basis of gender, Ilias et al. (2009) concluded that there is no difference in students' satisfaction towards service quality determinants and overall service quality on the basis of gender, Kumbhar, (2011) noticed that there is no difference in perception of service quality, perceived value and overall satisfaction in e-banking by gender and Phang et al. (2010) brought out that there is no significant difference between males and females in their preference of search/ deliberation or hedonic browsing

POST HOC

On the basis of significant result obtained within different occupational categories, a post hoc test was applied. Kruskal-Wallis (H Test) values indicated that significant difference exist between businessmen and servicemen with respect to perceived service quality dimensions of "access" ($H(1) = 7.262, p = 0.007$) and "credibility/security" ($H(1) = 7.288, p = 0.007$). Also significant difference was found between businessmen and students with respect to perceived service quality dimension of "credibility/security" ($H(1) = 5.231, p = 0.022$). However, no significant difference

Table 2. Factor analysis results

Dimensions	Cronbach Alpha	% of Variance	Items	Components			
				1	2	3	4
Reliability	.816	5.588	The quantity and quality of the product/service I received was exactly the same as that I ordered.	.077	.013	.732	.173
			The product/service I ordered was delivered to me within the time promised by the online retailer.	.267	.125	.723	.183
			The billing process was accurately handled and its records were kept accurately.	.266	.200	.731	.044
			The online retailer responded to my inquiry promptly.	.376	.273	.518	.222
			When the online retailer promised to e-mail or call me by a certain time, it did so.	.175	.419	.538	.246
Access	.828	7.334	The Web site showed its street and e-mail addresses, and telephone and fax numbers.	.229	.582	.339	.105
			If I want to, I could easily contact a customer service representative over the telephone.	.428	.592	.278	.154
			The online retailer offered multiple ordering options such as telephone or mail options.	.276	.720	.178	.035
			For more information, I could turn to the online retailer's chat rooms, bulletin boards, or others.	.104	.781	.049	.345
			The Web site had a message area for customer questions and comments.	.257	.572	.033	.466
Ease of Use/ Attentiveness	.805	41.490	The Web site address was easy to remember.	.580	.175	.378	.095
			The organization and structure of online catalogs were logical and easy to follow.	.722	.209	.214	.158
			All the terms and conditions (e.g. payment, warranty, return policies) were easy to read/understand.	.679	.186	.198	.199
			The contents in the Web site were easy to understand.	.808	.227	.168	.117
			I received a personal "thank you" note via e-mail or other media after I placed an order.	.506	.225	.152	.305
Credibility/ Security	.753	4.839	I felt secure in providing personal information for online purchase.	.417	.182	.205	.567
			I felt the risk associated with online transactions was low.	.269	.009	.183	.678
			The Web site showed how long the online retailer has been in this online business.	.036	.344	.068	.749
			I received special rewards and discounts as promised from doing business with the online retailer.	.099	.158	.278	.660

between servicemen and students with respect to perceived service quality dimensions of "access" and "credibility/security" was found (Table 5).

FUTURE RESEARCH DIRECTIONS

Present study tried to decipher the differences in perceived service quality (PSQ) within demo-

graphic characteristics of online shoppers in India and found that significant difference in perceived service quality (PSQ) exist within occupational categories. Finding "what constitutes an appealing e-service quality vis-à-vis occupation can be interesting research. Another, important and recent phenomenon to explore can be how "Webographics" (Grossnickle & Raskin, 2001; Kalia, 2016b)

can effect service quality or how demographics and webographics interact and affect e-service quality.

CONCLUSION AND IMPLICATIONS

This research establishes in general that no significant difference in perceived service quality (PSQ) exist within demographic characteristics

of online shoppers. However, one variable within which significant difference in perceived service quality (PSQ) exist is occupation. This study has various implications.

This is one of the first known study to probe the differences in perceived service quality (PSQ) within demographic characteristics of online shoppers in India. E-commerce growth in Asia-Pacific region will be driven by China, India and

Table 5. Post hoc: occupation and perceived service quality in online retail

Indonesia with the latter two markets clocking growth at 129.5% and 65.6%, respectively, in 2015 (eMarketer, 2015; Kalia et al., 2016). This signals that India is one of the most promising e-commerce market. Despite this fact there is dearth of research which examine the profiles of Asian e-shoppers (Kau, Tang, & Ghose, 2003).

Therefore, a study of Indian online shoppers' behaviour will help the e-businesses to contrive appropriate marketing strategies. Significant difference within occupational categories with respect to perceived service quality dimensions of "access" and "credibility/security" signals that one size can't fit all. Therefore, while proposing scales to measure perceived service quality researchers have to be more careful. Further, results of post hoc test indicated significant difference between businessmen and servicemen with respect to perceived service quality dimensions of "access" and "credibility/security" and difference between businessmen and students with respect to perceived service quality dimension of "credibility/security". This situation brings an opportunity for an online retailer to create a simplified website interface which appeals to all occupational categories. Secondly, web retailers can utilize the demographic information filled by the user during first time registration on the website to optimize the website according to visitors "preferences and abilities". Third, web retailers can create two or more websites and deploy cookies or other identifiers to direct user to the appropriate website.

On the basis of the fact that occupation is having an effect on service quality availed by online consumers, there is a possibility of developing different product and service offers that suits or surpass the preferences identified to be above average within an occupation (Hasslinger, Hodzic, & Opazo, 2007).

KEY TERMS AND DEFINITIONS

Access: Ease of contact and information gathering from the online retailer (Jun et al., 2004).

Attentiveness: The extent to which online retailers provide personalized services to their customers (Jun et al., 2004).

Credibility: Trustworthiness and believability of the online retailers (Jun et al., 2004).

Digital Buyers: Consumers who directly buy goods or services from a seller over the Internet using a web browser.

Ease of Use: Easy navigation of online systems, well-organized and well-structured online catalogs, concise contents, and easy-to-understand terms and conditions in e-retailers Web sites (Jun et al., 2004).

E-Retailer: Virtual merchant that sells goods and services to the public via online transactions.

E-Service Quality: The extent to which a website facilitates efficient and effective shopping, purchasing, and delivery (Valarie A Zeithaml et al., 2000).

Reliable/Prompt Response (2004): The ability to perform the promised service accurately dependably, promptly, and timely. Jun et al.

Security: Concerned with online transaction safety and customer privacy (Jun et al., 2004).

The Impact of Carbon Nanotubes and Graphene on Electronics Industry

E**Rafael Vargas-Bernal***Instituto Tecnológico Superior de Irapuato, Mexico***Gabriel Herrera-Pérez***Instituto Tecnológico Superior de Irapuato, Mexico***Margarita Tecpoyotl-Torres***Universidad Autónoma del Estado de Morelos, Mexico*

INTRODUCTION

A great technological opportunity has been introduced with the discovery of carbon nanomaterials where carbon nanotubes and graphene are their main representatives, which are completely involved in the science, technology and applications on new electronic devices, as an interesting alternative to those devices based on conventional semiconductor materials. They have attracted significantly attention of the scientific and industrial communities thanks to their unique electrical, optical, thermal, mechanical, and chemical properties. Nevertheless, carbon nanotubes and graphene due to their insignificant size, these require be homogeneously embedded into dielectric and light-weight, matrices, which are regularly of the polymeric type giving place to polymer-matrix composite materials (Das, 2013). Several models have been developed to predict the behavior of electrical conductivity of these composite materials based on carbon nanomaterials (Vargas-Bernal, 2013). Various chemical strategies for achieving synthesis of these composites have been proposed around the world, but these are not studied in this paper. The future trend in electronics industry consists in using individual carbon nanotubes and graphene sheets or set of them to design devices, circuits or systems. A lot of electronic devices have been fabricated based

on carbon nanotubes and graphene: field-effect transistors, diodes, analog and digital circuits, sensors (biosensors, gas sensors, etc.), solar cells, batteries, supercapacitors, flexible displays, etc. In this paper, the impact of the carbon nanotubes and graphene in electronic devices (discrete devices and/or integrated circuits), optoelectronic devices, photovoltaic devices, energy storage devices, and sensors, is briefly reviewed. This paper has been divided as follows: basic concepts about carbon nanotubes and graphene are described in section entitled Background. Next, different applications in the electronic industry are discussed in section entitled Applications of the Carbon Nanotube and Graphene. A comparison between the performance of the carbon nanotubes and graphene is presented in the next section. Future research directions are described in an additional section. Finally, conclusions about this study are given in the end section.

BACKGROUND

Carbon nanomaterials possess unique properties that can be exploited electrical, thermal, chemical and mechanically to provide applications in areas such as composite materials, energy storage and conversion, sensors, drug delivery, field emission devices, and nanoscale electronic components.

Three different morphologies between carbon nanomaterials can be distinguished: carbon nanotubes, fullerenes and graphene. Carbon nanotubes and graphene have been used more extensively in the electronic industry. Next, a brief description of their properties is made with the purpose of knowing the advantages of these materials for electronic applications. The basic concepts of each type of material have been separated for a better description.

Carbon Nanotubes

A carbon nanotube can be defined as a set of cylinder-shaped graphite sheets. Carbon nanotubes (CNTs) can be categorized by the number of graphite layers in their structure: Single-Wall Nanotubes (SWNTs) containing a single layer (see Figure 1), Double-Wall Nanotubes (DWNTs) with two layers, and Multi-Wall Nanotubes (MWNTs) that contain more of two layers (see Figure 2). Two main physical properties are associated directly with electronic applications: high thermal and electrical conductivity (Vargas-Bernal, 2012). Carbon nanotubes and their compounds exhibit extraordinary electrical properties useful for electronic organic materials, and can be used for a wide range of new and existing applications such as conductive plastics, flat-panel displays either as flexible displays or touch screens, micro-and nano-electronics (transistors), radar-absorbing coating, ultra-capacitors, solar cells, batteries with improved lifetime, hydrogen storage cells, conductors, smart textiles, electrochemical sensors, biosensors, and gas sensors. A more detailed study of their properties is found in Vargas-Bernal, 2012.

Graphene

Graphene is a two-dimensional allotrope of carbon with hexagonal lattice in atomic-scale, as shown in Figure 3 (Vargas-Bernal, 2015c). This material is a thin layer of pure carbon where each atom has four bonds, one σ -bond with each of its three neighbors and one π -bond that is oriented out the plane. Just

as the carbon nanotube, graphene has many extraordinary properties such as 100 times stronger than steel by weight, conducts heat and electricity with great efficiency and is almost transparent. From the electronic point of view, it presents the effect of a bipolar transistor, ballistic transport of electrical charge, and large quantum oscillations. A lot of electronic devices have been developed

Figure 1. Structure of the single-wall carbon nanotube (SWNT)

Figure 2. Structure of the multi-wall carbon nanotube (MWNT)

Figure 3. Structure of the graphene

using graphene in areas such as integrated circuits, sensors, optoelectronics, photovoltaics, and energy storage. A more detailed study of their properties is found in Vargas-Bernal, 2015c.

APPLICATIONS OF CARBON NANOTUBES AND GRAPHENE

Material scientists and engineers have been developing new architectures and devices based on carbon nanomaterials. A brief description of the multiple applications that carbon nanotubes and graphene have provided in the electronics industry is presented below. The applications of each material have been separated for a better description.

Carbon Nanotubes

Carbon nanotubes compounds are used in electronic packaging (IC trays and wafer carriers), transport trays for hard disk drives (HDD) and components, and ICs test and burn sockets, with the aim of providing protection from electrostatic discharges (ESD), homogeneous electrical conductivities on the surface, overheating, dimensional stability, recyclability, wafer hazing, ionic outgassing, static decay time, and high cleanliness requirements. Carbon nanotubes and graphene embedded in polymeric matrices can increase the efficiency of the electromagnetic interference (EMI) shielding to circuits operating to very high frequencies (Vargas-Bernal, 2015a). Moreover, carbon nanotubes represent a better alternative

to provide efficient and high-speed, electrical interconnects among devices within integrated circuit (Vargas-Bernal, 2015b), since they can offer reduction to the effects presented by copper, such as electromigration, large values of parasitic elements, large delays, and high thermal dissipation. Interconnect faults can be presented during device operation of integrated circuits originated by open-circuits and short-circuits. The possibility of self-repairing in integrated circuits is being studied through the use of carbon nanotubes dispersed in an insulating fluid to repair open-circuit interconnect faults by applying electric field across the gap between a pair of materials that have been disconnected (Sambandan, 2012).

Regularly, CNTs have been used as channels in (FET) field-effect transistors or CNTFETs either *p*-type or *n*-type (Vargas-Bernal, 2012). When CNTs are used to fabricate integrated circuits (ICs), there exist problems to obtain similar properties due to that metallic and semiconducting CNTs and both types of nanotubes can be found mixed during their synthesis process. A modularized method for fabricating ICs by using individual CNTs, has been proposed and experimentally demonstrated (Pei, 2014). Logic functions including AND, NOT, OR, NAND, NOR, and XOR have been designed based on carbon nanotubes. Digital circuits based on CNTFETs have the potential to improve the energy-delay product with respect to the conventional circuits based on silicon. The first computer based on CNTFETs was verified by running an operating system based on multitasks and was reviewed using 20 different instructions

of a commercial microprocessor with an instruction set of the type Interlocked Pipeline Stages (MIPS) (Shulaker, 2013).

The exhaustive use of portable and flexible systems has led to the development of power sources, such as primary batteries, rechargeable batteries (notebook computers and mobile phones), and supercapacitors (De Volder, 2013). These devices must be easily implemented in products such as smart clothings, flexible displays, transdermal delivery patches, etc. Carbon nanotubes embedded in a composite are considered very attractive materials for these applications due to their high electrical conductivity, large surface-to-volume ratio, as well as, by their thermal and mechanical properties (Wang, Z. 2014). Carbon nanotubes act as electrical fillers in thin films to generate lightweight current collectors and electrodes used in flexible alkaline batteries such as those based on lithium-ions (Li, S. 2011). Composites based on carbon nanotubes and vanadium oxide, can be used in binder-free flexible electrodes for supercapacitors, which offer large thickness, controlled porosity, high electrical conductivity and cyclic stability (Boukhalfa, 2012). In this application, carbon nanotubes reduce the electrical capacitance and allow the development of electrodes with high cycling rates for high-power applications, where charge-discharge processes of voltage are required in very short times. Three different groups of energy storage device are exploiting carbon nanotubes in their design: (1) industrial and stationary applications, (2) automotive and transportation applications, and (3) portable and personal electronics applications (Li, X. 2013).

Properties of carbon nanotubes such as large surface-to-volume ratio, high electrical conductivity and good catalytic activity are being applied in the development of counter electrodes in solar cells. By example, vertically aligned carbon nanotubes (VACNTs) possess high degree of order, controllability, and easy manipulation to be considered as strategic elements in energy conversion (Li, S. 2011) such as organic solar cells. Well-aligned CNTs improve the electrical properties

of the solar cells increasing the ion transport and reducing the charge transfer resistance.

CNTs have high mobility, high on/off ratio, excellent mechanical properties, and transparency. Therefore, they can be considered as a serious candidate to be used as base material to replace indium tin oxide (ITO) in electrodes of flexible displays (Yu, 2011). Devices for imaging based on visible light and X-ray can make use of organic photodetectors using thin-film transistors based on carbon nanotubes (Takahashi, 2013). These devices take advantage of the high mobility of carbon nanotube transistors for operating to low voltages, which enormously reduces the power consumption.

By example, potentiometric biosensors based on single-walled carbon nanotubes can behave as transducers ion-to-electron and aptamers can be used as recognition elements (Zelada-Guillén, 2012). This type of biosensors can be prepared either covalently or non-covalently, with the possibility of obtaining simplicity, stability, short analysis time and better detection limit or high sensitivity, respectively. The contribution of the carbon nanotubes is associated with the possibility of realizing detection in real-time and label-free, as well as high selectivity, high selectivity, which are difficult of achieving with other materials (Justino, 2013).

Graphene

Three main properties can be exploited in graphene for electronic applications: ultra-high mobility, low electric field, and high saturation velocity (Wang, Z.X. 2012). Thus, graphene is considered a promising material to design field-effect transistors (GFETs) used in high-frequency analog applications such as phase detectors, frequency doublers, and radio-frequency mixers (Lin, 2011). These transistors can achieve cutoff frequency of ~ 500 GHz due to the high mobility of carriers exploited in the graphene (Vargas-Bernal, 2015c). Even oscillator circuits based on devices operating to THz are being designed (Díaz, 2014), where

graphene is the electrical-channel to interconnect the terminals of drain and source of transistors. Frequency multipliers based on field-effect transistors (GFETs) were introduced in 2009, and these have been used as frequency-doubling devices (Ramón, 2012) operating in a 3-GHz bandwidth with low capacitance and high mobility for applications in security, short-range communication, and molecular spectroscopy.

Materials such as graphene present problems to be used as switch in logic circuits, since it has not cutoff current due to its ambipolar curve characteristic (Vargas-Bernal, 2015c), that is, a symmetric relation between I_{DS} and V_{GS} (drain-to-source current against gate-to-source voltage) is presented by their devices. Moreover, graphene is less prone than copper, to effects such as electromigration, low thermal conductivity, low mechanical strength, and high corrosion, which favor graphene to be considered as a better material for interconnects in integrated circuits (Prasad, 2014).

Graphene is being used to develop transparent electrodes to substitute those electrodes based on indium tin oxide (ITO) by taking advantage of ultrathin films with electrical and transparent behavior to the electrical current applied (Yu, 2011). Carbon nanotubes can be used in electron emission screens transverse based on graphene (Lei, 2013), with the aim of minimizing electrostatic shielding induced by the bulk substrate.

High sensitivity to the electrical current (semiconductor with bandgap zero) is exploited in biosensors based on graphene FETs, thanks to the absence of cutoff current and the characteristic of a high mobility of the electrical carriers during the phase of sensing (Pumera, 2011). Graphene due to their electro-activity and transparency is mainly used for enzymatic biosensing, DNA sensing, and immunosensing. Biosensors based on graphene FETs present low working potentials, high sensitivities, low detection limits, and long-term stabilities (Kuila, 2011).

Graphene has a relatively good, frequency response, and its light weight suggests their use in audio speakers and microphones as diaphragms

subjected to pressure waves in air by mechanically vibrating (Zhou, 2013). Highly sensitive Hall effect sensors can be developed thanks to the high electron mobility in the graphene, to be used in DC current transformers for special applications (Petruk, 2014) or scanning Hall probe microscopy (Sonusen, 2014).

Nowadays, a lot of interest is being put in the development of solar cells with low-cost production, simple fabrication and high energy conversion efficiency. A solar cell requires a counter electrode material with low sheet resistance, high reduction catalytic activity, good chemical stability, and low production costs. Graphene represents an alternative material to fabricate counter electrodes for solar cells with the possibility of matching properties such as electrical conductivity and the reduced catalytic activity found in platinum. Nitrogen-doped carbon nanomaterials can act as metal-free electrodes with electrocatalytic activity, long-term operation stability, and tolerance to effects such as crossover/poisoning, which can be exploited in the fabrication of solar cells (Xue, 2012). The performance of counter electrode is directly related with short-circuit current, open-circuit voltage, fill factor, and power conversion efficiency of a solar cell.

Graphene electrodes can be used to replace conventional electrodes based on indium tin oxide (ITO) for flexible displays (Yu, 2011). The use of graphene is due to their high transmittance, high optical transparency, high electrical conductivity and extraordinary mechanical properties (Jo, 2012). These electrodes can be used in transistors, light-emitting diodes, solar cells and flexible devices.

The use of graphene in photovoltaic devices, fuel cells, batteries, supercapacitors, and devices for hydrogen generation offer an interesting alternative to fulfill the increasing global energy demand (Bonaccorso, 2015). The advantage of using 2D materials is completely related with the ease of creating and designing layered artificial structures with multiple electrical properties. In particular, electrodes for supercapacitors and

lithium-ion batteries, gas storage tanks, as well as electrocatalysts and catalyst supports for fuel cells, are being developed (Candelaria, 2012). Different types of supercapacitors based on 2D structures have been proposed: electrochemical double-layer capacitors, pseudo-capacitors, and asymmetric supercapacitors (Huang, 2012). Moreover, graphene-based supercapacitors can be designed using five different types of nanoarchitectures (Salunkeh, 2014): (1) graphene doped with heteroatoms, (2) activated graphene, (3) composites based on metal oxide and graphene, (4) composites graphene-polymer, and (5) asymmetric supercapacitors based on graphene. Graphene is attractive as electrode material for energy storage thanks to their high specific surface area, interconnected porous structure, pore size similar to the electrolyte ions, good wettability toward the electrolyte, and high electrical conductivity.

COMPARISON BETWEEN CARBON NANOTUBES AND GRAPHENE

A great debate about which of the two allotropes have greater significance in the electronics industry has arisen among researchers who work either with developments based on carbon nanotubes or those working with graphene. CNTs as graphene are often regarded rivals in electronic applications, however, they are completely related, since carbon nanotubes are the zipped version of the graphene and their properties are compatible. Carbon nanotubes can be used as a reinforcing rebar for graphene during its manufacturing process. Moreover, the carbon nanotubes can be heated to produce graphene.

A performance comparison between FET devices based on carbon nanotubes and those based on graphene has shown that devices based on graphene have higher mobility and higher current density than those based on carbon nanotubes (Biswas, 2011). In addition, devices based on carbon nanotubes present a high on/off ratio with respect to those based on graphene. Metal electrodes are necessary to connect devices based on

CNTs, while that these are not required by devices based on graphene. Moreover, CNTs have lower transmittance, lower electrical conductivity and higher sheet resistance than graphene. However, both materials are highly flexible. Graphene and carbon nanotubes must be fully processed in a standard, reliable and repeatable manner to be used in consumer electronics on a large scale. In addition, they must demonstrate high yield, high speeds, and low power consumption to be led to the commercial applications.

The main obstacle to obtain practical applications with carbon nanotubes has been hampered by the intrinsic difficulty to connecting them within an electronic device. In the case of graphene, it has zero bandgap, which complicates their switching properties and therefore, its use in digital circuits.

FUTURE RESEARCH DIRECTIONS

Carbon nanotubes and graphene are being incorporated into existing and future electronic devices, and as a result they are being considered as strategic materials to substitute to the silicon in the next-generation of electronic products. Moreover, carbon nanomaterials have not one single area of application, and therefore, the researchers have found difficulty in knowing the limits that these materials have in the electronics industry. Thus, a lot of novel and interesting applications will be designed in the next twenty years, which will make use of carbon nanomaterials. During this time is hoped that money and expertise will be invested around of the world to develop and to research carbon nanomaterials applied in electronics industry.

Novel manufacturing processes must be developed to scale up them and lowering production costs to achieve the maximum performance of the graphene with respect to other materials. New methods to reduce power dissipation and increase the stability in devices directed to flexible electronics must be developed to lead to the carbon nanotubes into large-scale production. A significant decreasing in off-current magnitude, degree of

hysteresis, variation in threshold voltage and bias stress degradation presented by transistors based on carbon nanotubes must be achieved. For both materials, new strategies to develop composite or hybrid materials are necessary with the aim of guaranteeing the efficient use of carbon nanotubes and graphene by exploiting all their physical properties in different electronic applications.

CONCLUSION

This article provides a small review of the multiple applications of the carbon nanotubes and graphene, both in present as well as a projection of the future applications directed to the electronic sector. The next generation of electronic devices requires using materials with very high performance to fulfill the extraordinary requirements imposed by the novel applications. The graphene and carbon nanotube market directed to the electronics industry will rise by a CAGR of 60%. Thus, it is expected that an exponential boom related with research and technological development about graphene and carbon nanotubes could be prolonged until the year 2020. Physical properties such as thermo-electric conduction, high surface area to volume ratio, and mechanical strength have inspired a huge quantity of applications in electronic industry. Until now, a lot of applications have been designed and some of them are found in the industry. The success of the carbon nanomaterials depends of the ordering these materials at hierarchical scales, starting from large-scale dispersions and films and it finishes into ordered macrostructures and nanoscale devices in the near future.

ACKNOWLEDGMENT

The first author want thank the economical support to the research project financed by CONACYT-Mexico (152524) and by the Tecnológico Nacional de México under project 1671, both projects are associated with composites based on polymers and carbon nanotubes.

KEY TERMS AND DEFINITIONS

Carbon Nanomaterials: Nanostructures of carbon such as fullerenes, carbon nanotubes, nanofibers and graphene with unique physico-chemical properties with multiple technological applications.

Carbon Nanotubes: Allotropes of carbon with a cylindrical nanostructure of length-to-diameter of up to 132,000,000:1, which have unusual properties and valuable for nanotechnology, electronics, optics and other fields of materials science and technology.

Composites: Materials made from two or more constituents materials with significantly different physical and/or chemical properties, that when are combined, produce a material with different characteristics from the individual components.

Current Density: The electric current per unit area of cross section, and as vectorial quantity it has magnitude, direction, and sense.

Electrical Conductivity: The physical property that quantifies how strongly a given material opposes the flow of electrical current. A low resistivity indicates a material that readily allows the movement of electrical charge.

Electromagnetic Shielding: The action of reducing and/or isolating the electromagnetic field in a space by blocking the electromagnetic waves with barriers made of conductive and/or magnetic materials.

Graphene: A two-dimensional, crystalline allotrope of carbon whose atoms are densely packed in a regular sp^2 -bonded atomic-scale chicken wire (hexagonal) pattern composed by a one-atom thick layer of graphite.

IC Design: A subfield of electrical engineering, encompassing the particular logic and circuit

design techniques required to design integrated circuits, or ICs. ICs consist of miniaturized electronic devices built into an electrical network on a monolithic semiconductor substrate by photolithography.

Interconnect: A path of material that connects two elements or components in an IC, through which electrical current is transported.

Microelectronics: The study and manufacture (or microfabrication) of very small electronic designs and components normally in micrometer-scale or smaller by means of semiconductors.

Integrating Content Authentication Support in Media Services

Anastasia N. Katsaounidou

Aristotle University of Thessaloniki, Greece

Charalampos A. Dimoulas

Aristotle University of Thessaloniki, Greece

INTRODUCTION

The tremendous evolution of Information and Communication Technologies (ICT) and the low cost of the digital media devices have fueled the widespread expansion of the so-called User Generated Content (UGC). Social networking has become a popular way for users to meet and interact online through text and audiovisual content (photos, sounds, videos, etc.) that is produced and distributed in real time. Traditionally, users share news and multimodal content through social media, while simultaneously discover information on the Web. Among others, trust is considered to be one of the crucial factors of information capturing and dissemination. In the road from Web 2.0 to Web 3.0 and beyond, the quality and credibility of the recorded, shared and broadcasted content is controversial (Ljung & Wahlforss, 2008; Matsiola, Dimoulas, Kalliris & Veglis, 2015). Many (easy to use) multimedia capturing and processing tools (desktop applications and online /cloud services) are currently available and can be exploited literately at any time and place through mobile devices. This “processing at the fingertip” vision familiarizes average users with multimodal media production, processing and management tasks (Dimoulas, Veglis & Kalliris, 2014, 2015).

The domination of digital content over traditional analog media (i.e. films and tapes) has given rise to a number of new information security challenges. Digital content can be processed,

intentionally altered or falsified and redistributed relatively easy. This has important consequences for governmental, commercial, social and professional media organizations that rely on digital information (Stamm, Wu & Liu, 2013). Hence, mass communication and journalistic processes can be associated to unwanted content tampering, construction of fake evidences, sharing and propagation of untrue stories. In particular, the universality of “digital news reporting” has turned the evaluation of shared media into a field of prime importance, focusing on the automatic detection of manipulated and misused Web content (Mendoza, Poblete & Castillo, 2010). Its aim is to lay the basis for a future generation of tools that could assist media professionals in the process of verification. According to Figure 1, where the problem definition of the discussed topic is presented, media alteration involves all content types (text, images, audio, video, etc.) that are encountered in today’s Multimodal Media Assets (Dimoulas et al., 2014; Katsaounidou, 2016).

Content alteration can be conducted by anyone involved in the media production processes (media professionals, UGC–citizen journalist, etc.), as the bluish arrows in Figure 1 indicate. Once information falsification occurs without being noticed by the users, uncontrolled propagation of untrue stories may appear as a side effect of the contemporary need for timely and immediate informing. Hence, tampered information can be massively shared /propagated by end-users/con-

Figure 1. Problem definition: (multi)-media tampering as part of digital informing /infotainment

sumers (greenish-dotted arrows in Figure 1). The outmost target of the current chapter is to describe a collaborating model for overall supporting content authentication through dedicated computerized environments. In this context, users' and journalists' training (and their valuable feedback) holds a key role towards the integration and unification

of applicable media veracity services (and their associated learning resources). Thus, algorithms, methodologies and related ground-truth data-sets would be continuously updated, progressed and adapted to the specific needs of the encountered application scenarios.

BACKGROUND

Multimodal items can be evaluated and verified with a variety of methods. In principle, different authentication strategies are associated to various content entities, based on their distinct communication and operation attributes. Context-aware is the simplest authenticity analysis approach that can be applied in most media types, purposing to detect and pull abnormal information out of the content by exploiting human observation and cognition abilities (Silverman, 2013; Katsaounidou, 2016). Missing or unexpected shadows /reflections are common examples in the case of tampered images (Johnson & Farid, 2007; Farid, 2009; Krawetz, 2007). Syntax errors and/or absence of meaning indicate potential tampering in text messaging (Zubiaga & Ji, 2014). Abruptly interrupted background sound, unexpected intonation, and pitch changes form “novelty detection” indicators that reveal possible audio forgery regions (Dimoulas & Symeonidis, 2015; Gupta, Cho & Kuo, 2012; Hua, Zhang, Goh & Thing, 2016; Kotsakis, Mislou, Kalliris & Matsiola, 2015). Various combinations of the aforementioned audiovisual parameters are used in video /multimedia forgery detection (Angelov, Sadeghi, Tehran & Ramezani, 2011; Ho & Li, 2015; Kompatsiaris, Merialdo & Lian, 2012; Thakur, 2014). In this context, both machine-assisted and human computing methods exist (Figure 2), where the former utilize Natural Language Processing and Machine Learning algorithms, while the latter rely on crowdsourcing and experts’ suggestions (Silverman, 2013). Furthermore, semi-automated methods are used to detect cases in which the deception was committed on the semantic level, such as reusing older images (and other media) in different, irrelevant contexts. There are also approaches that do not exclusively rely on contextual or high-level information (i.e. format- and production-related metadata), but also examine structural features and content-based low level descriptors (i.e. frequency of letters/words in text; visual parameters like color, structure, shape; video motion activity metrics; audio

volume, spectral features, etc.) (Farid, 2009; Ho & Li, 2015; Katsaounidou, 2016; Thakur, 2014; Wang, 2009).

In practice, most of the aforementioned approaches require users’ active participation for drawing conclusions, while others incorporate learning-based decision systems (although they are not such common in real-world use scenarios). Nevertheless, enormous research progress has been conducted regarding the implementation of fully-/semi-automated content authentication algorithms. The purpose of the so-called forensic techniques is to trace a multimedia file processing history, to detect potential manipulation and generally to identify all possible forgeries. These methods can be grouped into five basic categories: a) device fingerprints-based that search for inconsistencies in the associated capturing patterns; b) compression- and coding-specific fingerprints that examine the presence of multiple compression levels; c) content statistics-based (i.e. image /noise histograms) that detect outliers indicating abnormal behavior; d) manipulation-specific fingerprints that investigate specific processing trails; and e) techniques that search for physical inconsistencies in the multimedia content (i.e. unexpected geometric artifacts).

As presented in Figure 1, tampering can be applied to any content entity that can be part of today’s multimedia information exchange. Following the above main directions, various methods and algorithms have been implemented for the different media types, both at research and application level. For instance, Twitter has become the quintessential platform to follow and be aware of breaking news and ongoing events. The fast pace of the tweeting streams favors the appearance of fake reports that often challenge the identification of accurate information to get rid of hoaxes. This endangers the trustability of tweets, as the veracity of some pieces of information can seem questionable on many occasions (Zubiaga & Ji, 2014). As Twitter grows more popular, new automations on ranking the credibility of the users and their posts are needed. Textual features, like the tweet-

length (number of containing characters/words), the frequency of question/exclamation marks or the number of the included uppercase characters, form typical evaluation parameters (Boididou, Papadopoulos, Kompatsiaris, Schifferes & Newman, 2014). Sentiment analysis (by counting the number of words with predefined emotional strength) could help in checking inconsistencies between the discussed topic and the composed messages, whereas user-related features can be also engaged (number of friends /followers, account verification status, etc.). Another approach is to classify posts in different topics, which has proven to increase authenticity recognition accuracy through statistical analysis. Thus, tweets' variance and the overall impact of noisy data are eliminated (Jin, Cao, Zhang & Zhang, 2015).

With millions of users capturing, recreating and sharing multimedia events, experiences and places around the world through social media, images and videos have flooded the Web, proving their power to influence society (Papadopoulos, Cesar, Shamma & Kelliher, 2015). Contemporary software has made the manipulation of photographs easier to carry out and harder to uncover than ever before, but technology also enables new methods of detecting doctored images. Aiming at restoring the wanted trust on digital images, Digital Image Forensics (DIF) has emerged as a sub-field of Digital Image Processing, taking advantage of the tradition and the pioneering research of the associated scientific societies. DIF has actually introduced and established the aforementioned categories of content-based media authentication (Farid, 2009): a) camera-based techniques that exploit artifacts, introduced by the camera lens, sensor, or on-chip post-processing (Johnson and Farid, 2007; Ho & Li, 2015); b) format-based techniques that leverage the statistical correlations, introduced by a specific lossy compression scheme (Farid, 2008; Luo, Qu, Huang, and Qiu, 2007; Ye, Sun & Chang, 2007); c) pixel-based techniques that search for related statistical anomalies at the pixel level (Mahdian & Saic, 2008; Zampoglou et al., 2015); d) model-based techniques that search

for specific tampering artifacts, detecting anomalies in the three-dimensional interaction between physical objects, light, and the camera (Johnson & Farid, 2007) e) geometric techniques that make measurements of objects in the world and their positions relative to the camera (Farid, 2009).

Nowadays, there is a rapidly growing number of audio and video files available on the Web, either on related social media (i.e. YouTube, Vimeo, SoundCloud, etc.) or through Web-sites of broadcasters, news and media organizations (Dimoulas et al., 2014, 2015; Dimoulas & Symeonidis, 2015; Ioannidou, Apostolidis, Collyda & Mezaris, 2015). While research on audio forgery detection has also gained significant attention, studies in this field are rather limited (compared to those in image and video). The aforementioned categories also apply in this case, with feature-based audio fingerprinting to be the most common single-side authentication approach; prior information can also be exploited (in the form of invisible metadata) in double-sided watermarking techniques (Dimoulas & Symeonidis, 2015; Gupta et al., 2012; Ho & Li, 2015; Hua et al. 2016). Likewise, video forgery detection can engage both active (double-sided) and passive (single-sided) approaches (Sowmya & Chennamma, 2015). Watermarking and signature-related techniques fall into the former category, while context- and content-based evaluation is engaged in the latter. Video analysis is usually conducted at pixel, block, frame and scene level, searching for all spatial, temporal and spatiotemporal alterations. Spatial (intra-frame) tampering is similar to image-forgery, where foreground/background object attack might occur (removal, addition, modification, etc.); it is usually detected through image/frame statistics (spatial features). Motion-pictures tinkering includes frames (and objects) drop/deletion, copy, insertion, swapping and shuffling, where motion-related temporal and spatiotemporal features can be also exploited (Sowmya & Chennamma, 2015; Ho & Li, 2015; Thakur, 2014; Richao, Gaobo & Ningbo, 2014; Wang, Li & Ma, 2014; Wang, 2009). Video authentication is more difficult than image and audio

counterparts, due to the higher (spatiotemporal) dimension of the video-sequences that is associated to increased data-rates and computational load demands. For similar reasons, video tampering is also more difficult and less effective compared to image forgery (it takes much more processing/time or else alterations could be more easily detected).

MEDIA AUTHENTICATION DEMANDS IN REAL-WORLD PRACTICAL SCENARIOS

Media Veracity Methods and Tools: Issues, Controversies, Problems

Despite the outstanding progress that has been conducted in research terms, content forgery tools that can be useful to media users and professionals are quite limited. Automated authentication algorithms can detect a huge amount of content when it comes to queries on breaking news events, but arguably only human-beings can sift through (in real time) and make sense of content in an efficient way, (Silverman, 2013). Adopting best practices suggested by the Verification handbook, various services such as the Crowd Crafting¹ and Verily² platforms can be exploited in the direction of context-aware crowd computing approach. Additional, tools have been implemented to find contact details and profiles of users who are active on social media, such as WebMii³, which can be used to identify fake profiles. Findexif.com⁴ and Jeffrey's Exif Viewer⁵ can be utilized in device-fingerprint forgery detection. Both reveal photos' Interchange Information (Exchangeable Image File, known as EXIF) that most JPEG-storing digital cameras use for annotating common capturing parameters (shutter speed, exposure, F number, etc.). Specialized DIF tools are also available through online/free platforms dealing with most image forgery problems/techniques (e.g. Forensically⁶, created by Jonas Wagner; Multimedia Forensics Tool⁷, implemented in the framework of the REVEAL⁸ project). Far less

activity is observed regarding audio and video veracity services. Characteristic examples are the Forensic Audio Analysis System⁹ with the EdiTracker¹⁰ plugin (in the former case) and the ongoing project InVID¹¹ (in the latter). InVID authenticates the reliability and accuracy of news-worthy videos through shot/scene segmentation and concept detection strategies. Hence, despite the availability of the aforementioned applications/services, there is lack of an integrated system (both in term of methods and content modalities) for supporting media authentication from all of its aspects in real world scenarios (as indicated in the right part of Figure 2).

Consequently, media professionals and citizen journalists still rely mostly on traditional methods while verifying news reporting information (and its dissemination). The arising problem derives from the complexity of the algorithms and their outputs that require technical know-how and "digital literacy", in order to be comprehensible and usable by the average user. Indeed, recent research on image authenticity evaluation confirmed the expected difficulties and weaknesses of those services, while it also revealed that most of participants (including active UGC/Web-2.0 users and media professionals) were not even aware of the existence of such tools (Katsaounidou, 2016). It was also proven that authentication recognition accuracy increases when involved users are properly instructed and truly exploit related algorithms (proving their usefulness), especially after being familiarized and comprehend the provided indications. Nevertheless, while most of the forgeries are generally detected by at least one method, the achieved authentication performance remains at low level when algorithms are used separately, increasing also the appearance of false positive results (cases where genuine images are considered to be fake /tampered). Hence, considering the harmful consequences of falsified news and media content propagation, there is a profound need for such advantageous techniques to be combined into an integrated framework.

Figure 2. Available media forgery methods /modalities and the need for integration

Solutions and Recommendations: Integrating Media Authentication Support

The preceding analysis advocates that state-of-research content authentication algorithms have to be deployed in real-world practical scenarios, accommodating various users' and media application needs. All media experts, professional journalists and ordinary users should be trained in the "fresh technologies" shaping this new field. Indeed, the implementation of such a learning framework should put great emphasis on receiving the wanted feedback, with ultimate goal the collaborative development, upgrading, integration and maintenance of unified content verification services through user-friendly (online) environments. For instance, unification, in terms of formalized visualization and representation of the extracted results, is really necessary for the average user, who has difficulties in comprehending the scientific and operational characteristics of the algorithms, therefore in interpreting the provided indications. In this way, more standardized corrective remarks can be obtained through users' interaction as useful feedback towards algorithmic and interfacing

improvements. Furthermore, integration is also desirable for the various content types of today's multimodal posts and shares, where multiple tools need to be applied for the different modalities in a collaborative fashion. Also, it would be really useful to be able to track the accuracy of all the available methods/modalities with respect to the various thematic topics and content categories. In this context, more accurate decision making would be possible by selecting the method expecting to have optimum performance in each specific case, or by properly combining/weighting multiple algorithms via modular-ensemble systems.

It has been observed that manipulated content overwhelms Internet and often reappears on the agenda at different time-instances, drawing users' attention and having impact on public opinion. For this reason, the construction of an online repository would be quite useful in the direction of documenting known forgery cases, helping users to be aware of the already detected falsified information. These data-sets could be also exploited in best-practice adoption and training-scenarios, aiming at conveying the current know-how possessed by experts to regular users. As presented in Figure 3, average users, media professionals and forgery

Figure 3. The proposed integration for supporting media authentication

specialists are being part of the proposed Media Authentication Network, purposing to acquire, exchange and disseminate knowledge on content authenticity and media veracity strategies. The recommended model implicates continuous analysis, classification and documentation of the recorded samples, fed by the associated submissions, queries and comments on both authentic and manipulated content, deriving from all the involved users' feedback. Additional classification metadata can be inserted in terms of subject/topic, creators' and media organizations identity, location (geo-tag) and time information, re-share's methods, the associated falsifying occurrence ratings and others. Hence, a gradually constructed ground-truth would be available for future reference and use, where, besides context-aware authentication, algorithmic and hybrid approaches could be also supported through training and feedback processes.

FUTURE RESEARCH DIRECTIONS

On the road to Web 3.0 and beyond, the ultimate goal is to be able to deploy semantic processes for recognizing and semantically conceptualizing digital content at various levels. Nowadays many

related services are continuously launched and progressed, which apparently would have a positive impact on the efficiency of future media veracity tools. For instance, this can be served through content recognition and concept understanding, followed by the selection of category-optimal forgery detection algorithms, as previously explained. Also, context inconsistencies between the extracted semantics and the associated results of the various authentication methods and algorithms (or between the content artifacts of the various modalities) are expected to be very helpful. For instance, language and emotion classification outcomes can be evaluated in term of consistency with the surrounding environment and context of the events (Kotsakis et al., 2014, 2015). Similarly, content recognition can be exploited for matching and aligning different streams representing the same multimedia event, favoring semantic metadata propagation of matched media, from one to another (Dimoulas & Symeonidis, 2015). Hence, media veracity metadata can be initially extracted from documents that can be more easily and accurately analyzed in terms of authenticity evaluation and then propagated to all the linked data. Progress on related fields like human biometric analysis and contemporary time-, location- and context-aware

ubiquitous technologies could further expedite authentication support, through the extraction and enhancement of user- and situation-related metadata (i.e. who, where, what, when).

From a different perspective, upcoming semantic recognition and conceptualization services are mostly based on the use of machine learning algorithms, heavily relying on the availability of appropriate ground-truth data-sets. Hence, dedicated labeling could be extracted by the proposed model /repository that could serve in assisting the implementation /training of general-purpose semantic services. Considering that massive content is associated to social media posts and shares, it is obvious that enormous amounts of annotations can be also obtained in various levels, through direct and indirect tasks (i.e. registering users' selections on specific browsing /interacting scenarios) (Dimoulas et al., 2015). Hence, relatively easily obtained ground-truth could be further exploited in other digital content forgery applications (i.e. law and justice affairs, sports, politics, sciences, show-biz, history and culture, health and medicine, and others). On the other hand, as technology progresses, content tampering becomes easier and more effective, while anti-forensic techniques also evolve, aiming at preventing or hardening proper forensic investigation. Similarly, the upcoming trend of Robot Journalism (i.e. gathering and publishing news/data without human intervention) can be turned into a subject of information tampering (both unintentionally and deliberately), making even more crucial the need for proper users' informing/training. Thus, a continuous effort is needed in order to be able to keep up with the pace of the new developments, therefore to efficiently deploy media authentication, which can be also considered as a proof of concept for the proposed model.

CONCLUSION

The present chapter examines a variety of content authentication methods that are intended for

helping average users and media professionals in securing themselves by fake information and preventing the spread of misinformation. Undoubtedly, there has been an exponential progress in content veracity strategies, by implementing dedicated fully-/semi-automated authenticity evaluation techniques. However, this know-how has been mainly developed at research level, without providing related straightforward tools to the users involved in media production and consumption services, in various real-world scenarios. Hence, there is an urgent need for further supporting media authentication by exploiting all the available methods in properly integrated computerized environments. The implementation of a Media Authentication Network is proposed, where on-demand training (and feedback) on the new technologies is considered of major importance, enabling users to collaborate with media and forgery experts towards adoption, refinement and widespread dissemination of best practices. These synergies would also propel better comprehension of the involved tools and algorithms, in order to be fully exploited in practice, gaining valuable feedback for further improvements. Thus, a continuously updated online repository, containing documented examples, learning resources and media veracity computing services, could be adaptively accommodated in order to better support the specific needs of the different users, in various application scenarios.

KEY TERMS AND DEFINITIONS

Anti-Forensics: Anti-forensic techniques are content actions aiming at preventing or hardening proper forensic investigation.

Biometrics: Biometric systems measure and analyze various persons’ psycho-physiological parameters (fingerprint, face-expressions, stress-factors, etc.) aiming at evaluating their behavioral status in various cognitive task and/or surveillance scenarios.

Computer Forensics Science: A research field focusing on content examination with the aim of identifying, preserving and recovering the truth of digital media.

Digital Forensics: A branch of forensic science encompassing the recovery and investigation of material found in digital devices, often in relation to computer crime.

Digital Image Forensics (DIF): This field emerged as a sub-field of Digital Image Processing (DIP), aiming at providing tools for images tampering investigation.

Machine Learning (ML): Scientific discipline that investigates algorithms and methods aiming at giving machines the ability to learn from experience (without being explicitly programmed), in order to respond autonomously on specific tasks and automate various data-handling processes.

Multimodal Media Assets (MMA): The kind of multimedia content commonly encountered in today's posts and shares, incorporating mixed time-based and page-based media (text, images, audio, video, etc.) along with their metadata.

Natural Language Processing (NLP): scientific discipline utilizing Machine Learning and Computational Linguistics, aiming at giving

computers/machines the ability to perceptually interact through human (natural) languages.

User Generated Content (UGC): Any form of content created and shared by users of an online system or service.

IT Service Management Architectures

Torben Tambo

Aarhus University, Denmark

Jacob Filtenborg

Aarhus University, Denmark

INTRODUCTION

In a world of ever increasing importance of digital business models with strong elements of outsourcing, heterogeneous IT landscapes, and cloud services, IT service management (ITSM) must be founded on strong approaches of governance (Pröhl & Zarnekow, 2015; Iden & Eikebrokk, 2013; Ali et al., 2013;). Digital business models mean that companies potentially both can act as providers and users of IT services (Richardson & Mahfouz, 2014), and companies change from being suppliers or distributors of traditional physical product to provide or rely on a mesh of digital services. ITSM architectures cover the system architecture, information architecture, and enterprise architecture enabling IT services and IT services deliverables (Braun & Winter, 2007; Eder & Nag, 2001). Important for these architectures are the alignment with fundamental operational agreements, mainly Service Level Agreements (SLA) and operational frameworks such as Information Technology Information Library (ITIL) (Holland, 2015), COBIT (Saran, 2015), Microsoft MOF, HP ITSM and IBM ITPM (Iden & Eidebrokk, 2013). ITSM architectures most generally reflect the services stipulated by ITIL (Gama et al., 2013) although an extension of ITIL is seen with the introduction of the Service Integration and Management (SIAM) framework (Armes et al., 2015).

As many ITSM architectures are relatively well-defined on single management dimensions of ITIL, there is a general lack of architectural under-

standing across the different service management dimensions. Complex services crossing several ITIL management layers and other added services suffer from lack of a single ITSM architecture with this resulting in customized and hard-coded solutions for monitoring, reporting and enabling of transparency. Data collection for e.g. incident management might remain loosely connected to management systems for continuity, capacity or security management. Configuration Management DataBases (CMDB) and Service Catalogues are widely expected to connect services and management systems, but are often incomplete, inconsistent, under-managed, over-managed, overaged or lagging behind with precision.

The claim of this article is that the modern digital business must connect all its silos of service management systems in well planned architectural systems potentially also connected to the general enterprise architecture of the company.

This article is based on a case study in a major IT services provider, where it was realized that service management had grown apart from the enterprise architecture in terms of highly customized solutions and services not using sufficient scale of magnitude and uniformity of processes, services and reporting. A services architecture was made from available but disjoint sources in order to create transparency and efficiency in the services production. The services architecture is important to realize digital business models whether being producer of IT services as core business or being a digitally enabled business.

BACKGROUND

Most companies and organizations are increasingly dependent on information technology (IT) and IT services. As technology is becoming more distant and commoditized in the form of cloud services and fragmented between highly specialized vendors, management of services is getting comparatively more critical (Amanatullah et al., 2013). IT Service Management (ITSM) is thus the adaptation of the right services to the right business.

Services Fundamentals

The fundamental concept of creation of business value of IT is normally expressed as services (Lahtela et al., 2014). Services are building blocks of service systems. Services are inclined to interact with work as work systems (Alter, 2014a; Alter, 2014b) with a need to recognize ‘service’ as a highly multi-faceted term with numerous contextually-linked meanings. Moreover, services are defined by constituting elements of technology, practices, and skills and operable elements of initiation, execution and termination. Frameworks such as ITIL (Holland, 2015; Randone, 2012; Kaschanki & Toland, 2006) define services from levels of criticality and impact for business, especially drawing up the concept of Service Level Agreement (SLA) that over time has transcended from IT into business in general.

Quality of service (QoS), and henceforth fulfillment of business expectations, is fundamentally defined as the ability to meet SLA KPI’s (Dubois, 2014). QoS is thus not a subjective judgement but an objective, agreed, defined fact normally also being measurable. This leaves the subjective issue open. Popularly, there can be disputes on services as they are subjectively perceived “bad”, but do meet SLA. Garschhammer et al. (2001) define QoS as independent of providers and clients, but at the same level as service access, service functionality and service management. QoS consists the several elements of service expectations stipulated in

the SLA, e.g. availability, scalability – capacity management, ‘detect and correct’, and the two ‘front ends’ of ITIL: Incident management and problem management (Soomro & Hesson, 2012; Franke et al., 2014).

Service design is the activity of composing the right set of services from available or new services based on business customs, technologies, people, skills and context. Garschhammer et al. (2001) discuss service design based on telecom services and describe the service design process as based on a service life-cycle analysis, mapping interactions, describing functional attributes, defining roles, object and relations, and ending with a service model.

In designing services, appropriate design for the optimal solution of a given requirement is normally the point of departure. It is however much more critical to ensure reusability of services through harmonization, standardization, adaptation, scalability and security. Wullenweber et al. (2008) discuss standardization of services in relation to potential outsourcing thereby underlining the importance of services being movable across organizational barriers.

Infrastructure and Enterprise Architecture Fundamentals

Infrastructures have traditionally seen as the supporting structures for IT services consisting of technology and assets (Ali et al., 2013; Närman et al., 2014). Infrastructures are in such a perspective company internal, also considering Alter’s Work System Model (Alter, 2014a). Increasingly benefits have been realized from outsourcing of parts and pieces of infrastructure. Especially application management, server-services, security services, and more labor intensive services of incident management and call centers.

Cloud architectures and service virtualization mean that services are provided by a shared infrastructure. Technical as well as human efforts in services are thus to be considered as relative mobile which in turn can be discussed as fragmentation

Figure 1. The EA3 cube of enterprise architecture methodology
Bernard, 2012.

of services, distance between the place of service delivery and service consumption.

Enterprise architecture is focused on documenting and managing change in the relationship between business strategy, organization and technology (Zachman, 1996; Bernard, 2012). Enterprise architecture connects technology from its lowest level and upwards towards products and services as described in Figure 1.

TOGAF is an industry leading framework for prescribing change processes in structured and documented phases (Vicente et al., 2013a) using a cyclical approach to ensure continuous update and improvement of the enterprise architecture documentation. Archimate is a modelling language for describing processes and artefacts associated with enterprise architecture modelling and management processes (Band et al., 2015; Vicente et al., 2013b).

Services, Architectures, and State of the Art

The literature and cases on applying enterprise architecture on IT service provider organizations is limited. Braun & Winter (2007) discuss enterprise architecture and services integration but with the main aim of extending enterprise architecture with

service of service-oriented architecture (SOA), i.e. this is more a technical design than a strategic supplier perspective.

Conceptual integration of enterprise architecture and ITIL is suggested by Gama et al. (2014) to ensure simplification of IT governance processes and avoid risks of ambiguity in providing services (Jäntti & Hotti, 2015).

ITIL has largely been regarded as state of the art for production of IT services. Especially in its full and idealized implementation, ITIL provide a heavily detailed and extensive framework on the operational foundations and best practices within IT services. It is worth noticing that ITIL is a proposition for IT services and normally needs local adaption to the service context needed. In that sense ITIL address the key operational requirements, but it also address transitions with due reflections on both infrastructure and service transition risk management, transparency, mitigation of problems, and stabilization.

MAIN FOCUS

According to the enterprise architecture model above, the perspective of this article is that IT beneficially can be regarded as a line-of-business

by its own in any aggregate of enterprise and thereby IT logically must have an enterprise architecture of its own. Key elements of this is the commercial, organizational, HR and technological transformation from the fragment/value-provider perspective of IT service providers (internal or external) and to reviewing own capabilities and competencies with the methodologies normally reserved for analysis and solutions to clients.

Issues, Controversies, Problems

Of main caveats for IT transformation are appropriate self-perceptions of precision and specificity of its services and added value to own business models as well as clients' business models. This is complicated by IT landscapes as generally being predominantly heterogeneous (Heininger et al., 2013) with long development time and long phase out time of given services and technologies. A closer relation between service catalogues and enterprise architecture is worthwhile investigating.

Combinations of requirements from fragmented clients, in case of services providers, or extent and differentiation of value chains, in case of internal providers, create complexity given variations in infrastructure, applications and financial restrictions. Aggregate services are thus more complex – and the solution is probably not to divest service fragments to yet new providers.

Seen from provider perspective, services clients are likely to be less and less loyal, aim for perceived commoditized services, and accept multi-vendor service landscapes with having full insight into consequences for complexity and necessary capabilities for governance. Here, ITIL will come to an end in management of complexity, and SIAM-like approaches must be considered.

So, the aim is to investigate the formation of architectures positively supporting ITSM in multi-client, multi-vendor landscapes. Below a case study is presented using a transformational process of a service provider seeking to manage complexity and transformation.

Case Study

A larger IT services provider, anonymized as ABIT, had been transitioning from a few clients to engage with several larger clients across Europe. ABIT had a generally good reputation in the market mainly due to highly customized service contracts, adaptive approach to customers momentary need, and even more customized report services. Services included most of the ITIL palette of services and associated systems operations and management activities. ABIT could also deliver software development services, but this is more a secondary activity. The highly customized service contracts had impacts in the organization in form of:

1. Complex reporting of SLAs to clients that was customized and labor intensive – more than 3500 KPIs were identified.
2. There was not a direct translation from ITSM, systems management software and infrastructural monitoring to a reporting system.
3. Manually processed SLA reports were delivered to clients retrospectively with no online reporting to clients.
4. Reporting data were ambiguous and frequently disputed both internally in ABIT and between clients and ABIT.

To overcome the issues of IT services monitoring and reporting, ABIT started to review the options for design of an enterprise architecture for its IT services. Thus ABIT's approach had typically been to review its services as an external extension of the clients' enterprise architecture, e.g. applications and services, information and data. Figure 2 is describing the architectural draft with the rationale that Service Catalogue-based SLAs drive business processes either in terms of ongoing and agreed services, but also transformational projects and projects related to problem management.

Figure 2. Relation between ITSM architectures of services and change

The realized issue was to review itself as a producing company that could benefit from an enterprise architecture approach. According to the principles of Ross et al. (2006) it was decided as critical to obtain a unified enterprise architectural strategy for the mainline of internal operations although with option to adapt to a diversified enterprise architecture in various critical client driven areas.

As the immediate objective of the company was to develop a unified enterprise architecture for reporting on services, it was necessary to define a relevant starting point. As an IT services provider, ABIT sells server, storage and network capacity along with management and support services for standard and bespoke software systems. This defines key artifacts of the enterprise architecture. The services are operated via a number of management systems. Operations management systems (ITOM) monitor infrastructure. ITSM systems register mainly incidents and problem management. The individual customer service

contracts, SLA KPI's, and the available service catalog form a level of business objectives that are to be executed through ITOM and ITSM systems. Portfolio management, long-term planning and transitional projects are managed in non-standardized systems using mostly ad-hoc project models, although transitional initiatives draw on inspiration from both ITIL and TOGAF.

Results

The case led to a number of significant achievements for ABIT. The unified enterprise architecture not only created a more efficient service delivery organization, it also created more precise and well-defined services of the IT Service Catalogue. It was realized that the diversified approach to customers was actually not what the customers preferred; the customers preferred clear links between expected services, the providers ability to produce these services, and the report provided on the services. More specifically, the hours spend

on reporting to each customer was drastically reduced – in a broad scale from 100 to 10 hours per customer either per month or per quarter. This left more resources to qualified services of getting better insight in the customers' expectations and needs. Identified new needs or identified obsolete services could far better be presented to customers combining the IT Service Catalogue and the IT Service Management Enterprise Architecture.

SOLUTIONS AND RECOMMENDATIONS

The tradition among IT service providers to consider themselves as a production apparatus with a distinct enterprise architecture is relatively new and remain yet to permeate industry. It is a question of a redefined mindset: To perceive IT as a business with a business model of its own rather than see IT as a fragment of other business models. Typically, IT has expressed itself in terms of solutions for improvement of other business models, but in this context, IT can improve IT.

From the case study, a generalized approach can be derived. The approach can be described as a transition from the fragmented and client-only-centric to the IT-intrinsic perception of the IT service provider as a fully workable and responsible provider with its own enterprise architecture.

The approach consisted of a set of metaprocesses, illustrated in figure 3. In clear terms these processes entailed the following activities:

1. Define the organizational structure of the client organization, thereafter define the providing organization of ABIT. The overlap between these formed the focal organization of the intended enterprise architecture, with the sum of the providing organization as the target organization for the to-be enterprise architecture.
2. Metaprocesses were defined in terms of
 - a. Service catalogue development and service catalogue services measurability (SLA).
 - b. CMDB artefact (CI – configuration items) development and relations between CI and the service catalogue.
 - c. The organizational responsibility, capability and alignment on governance of metaprocesses.
 - d. The customer service design according to requested services, service catalogue and ABIT's CMDB infrastructure (unified).
 - e. The customer service SLA (diversified).
3. Found services in processes described using BPMN notation.
4. Convert artefacts to a UML representation as an enterprise architecture repository.
5. Combine metaprocesses, the BPMN, and the UML in Archimate to represent the final enterprise architecture.
6. From known SLA KPI's, a relevant reporting and analytics framework can be created combining distributed service repositories.

Table 1.

Strategy	To provide leading and cost-efficient IT services to high-end customers
Business	Appropriately combine skills, processes, technologies, standards and customer collaboration
Information	Any SLA related to ITSM, ITOM or change processes must be represented in the information repository of enterprise. Any process and technology should be reviewed as information provider to the overall management processes
Systems	There should be a direct connection between service catalogues and systems although systems need also
Networks	Largely describing connectivity between place-of-use and place-of-make, thereby supporting cloud, distributed and local service architecture

Figure 3. Relationship between organization, metaprocesses and enterprise architecture formation

The approach is indicated in Figure 3.

Using Bernard's (2012) EA3 model this would be expressed as shown in Table 1.

Importantly is to express the designed enterprise architecture as both documentation and planning. In terms of IT services organizations, it is critical to extend this with reasonable considerations of the interactions, relationships and agreements with the client organizations mainly expressed in terms of SLA and service catalogues.

Furthermore, validation of the stated models is by itself fundamental. Below is the model developed from the case study above. The model is

narrowly focused on iteratively ensuring a precise relationship between the organizational entity of the delivered services, the services as defined by the service catalogue, the SLA, the KPI, and reactive processes initiating service execution, data collection, and data reporting.

An excerpt of the developed processes supporting the ITSM enterprise architecture is illustrated in Figure 4.

Figure 4 is highlighting that services are managed as a continuous flow of data underpinning the KPIs of the service catalogue. A number of organizational roles within ABIT were clarified as

Figure 4. Service delivery reporting and adaptation

a part of the process. Especially ‘process managers’ have technical responsibilities, whereas ‘service delivery managers’ have client responsibilities. SLA KPIs are in such a way constructed to continuously confirm the validity of the designed enterprise architecture, or give reason to modify or update the enterprise architecture.

The architecture of ITSM should follow the general architecture of the desired business objectives. In reshaping ITSM through architectural thinking, it is highly a matter of having IT “taking its own medicine”, and reflect specifically on:

- Accept dual EA purpose: One of the service provider, one of the impact of a service to the clients business.
- Exploit IT-takeaways to IT business, e.g. “big data analytics on ITSM and ITOM”, “BPM on IT processes”, “CRM analytics on service quality”.
- Aim for unification rather than diversification.

At the longer term, ABIT intends to adapt to the SIAM (Armes et al., 2015) framework. Here ABIT can get a clearer picture of service constructs, definition of service delivery complexity, and requirements for collaborative service delivery environments. SIAM can overcome the lack of understanding of complexity in ITIL – although ITIL’s definitions and obligations of roles remain precious. SIAM can probably not ensure the architectural uniformity at the inner lines of ABIT. Therefore it is still valuable to consider enterprise architectures for ITSM providers.

FUTURE RESEARCH DIRECTIONS

The case study above is more focused on ITIL than SIAM (Armes et al., 2015). Future research can benefit by including aspects of SIAM in to the architectural design, i.e.

- Multi-vendor services,

- Supplier management including supplier life-cycle management,
- End-to-end service management,
- Advanced portfolios and service catalogs,
- Integrated toolsets,
- Providers insight in clients operations.

A key issue in the presented study is that the focal/client companies are likely not to relate themselves deeply into the ITSM reporting but rather to the providers’ ability to “foresee the unexpected”, e.g. shifts in load, new security threats, patching conflicts. As the outlined architectural guidelines are mostly focused on quantitative, “as-is” reporting, new approaches would be needed to support advanced prediction analytics, early warnings, and automated remediation. Such systems and solutions do exist (SAP, 2016; Oracle, 2016), but are largely product-centric, disconnected from the overall ITSM landscape, and not taking complex, distributed SIAM multi-vendor service environments into account.

CONCLUSION

This article has described the development of a series of approaches in moving from fragmented and ad hoc based IT service management to a unified approach of enterprise architecture for IT service management. The architecture included an information architecture made in UML. A business process architecture made in BPMN and a modelling approach in Archimate. The resulting IT Service Management architecture can serve as a template for the creation of overarching service architectures for governance of operational and monitoring technologies linking technology and services.

This article demonstrates the value of considering IT services as a full and independent business of its own with an appropriate enterprise architecture. This opposes the view traditionally offered by IT service vendors as having managing fragments of clients’ business models without full

inclusion in the clients enterprise architecture, and likewise without specifically to utilize enterprise architectural views in the providers own line of business. The Ross et al. (2006) operating model of Unification is making strongest sense related to standardized business processes of ITIL, ISO2000 and common Operations Frameworks like MOF

A positive learning is that the suggested approach is as applicable to in-house IT operations as it is to IT service providers. In-house IT as well as service providers have to deal with fragmentation of vendors and sprawling service catalogues, whereas the overall service requester must be supported with appropriate means and tools for knowing, what is being paid for and what to expect. The recently introduced IT4IT framework (Josey, 2015) furthermore supports the findings of the necessity of designing IT for IT.

KEY TERMS AND DEFINITIONS

Architecture: In Information Systems research, a fundamental or aggregated artefact of technological, organizational and processual character.

CMDB: Configuration Management Database, the key repository in ITIL for items to be serviced. The individual items are known as CI, Configuration Items. The CMDB can be supported by specialized or general software. Some items can be retrieved automatically via automated networked IT services information collection, e.g. using the SNMP protocol.

Enterprise Architecture: The business activity of ensuring appropriate relationships between business strategy, and supporting technologies. Enterprise Architecture is mostly connected to

information technology, but is not limited to this. Any relationship between business and technology can be encompassed in enterprise architecture. The activities are generally two-fold: To document the existing portfolio of technology, and to plan technological transitions.

IT Service Catalogue: The service catalogue is a “handbook” describing, what can be delivered of services from any, in-house or external, IT service provider. The service catalogue aims at adjusting expectations between requesters and providers and contributes to control cost of services. Furthermore, providers are “protected” from supplying services, although desired by the client, where no services exist e.g. caused by competencies, technology, logistics.

IT Service Management: ITSM is the discipline of organizing and managing IT services to meet expectations of clients and ensure budgetary objectives. ITSM entails long term planning to safeguard relevant technology and human resources. Furthermore, ITSM is aimed at adapting the IT Service Catalogue to fit the demand from clients and the given financial constraints.

ITIL: Information Technology Information Library. A management framework for IT services and infrastructure management. Originally developed within the UK government, but as of today, a de facto standard globally for IT services provision and governance. ITIL is mostly adapted to local requirements and is rarely found fully and precisely implemented. ITIL is reflected in the ISO/IEC 20000 standard.

SIAM: Service Integration and Management – a governance framework for complex, multi-vendor IT services environments. SIAM is designed to overcome issues with ITIL on responsibilities, contract management, cross-organizational collaboration and heterogeneous environments.

Business Intelligence Impacts on Design of Enterprise Systems

Saeed Rouhani

University of Tehran, Iran

Dusanka Milorad Lecic

Levi9 Global Sourcing Balkan, Serbia

INTRODUCTION

In this information age, the approach to decision support as an individual system, such as decision-support systems (DSS), has been replaced by a new viewpoint of intelligent software and systems (Mehdi Ghazanfari, Rouhani, Jafari, & Taghavifard, 2009). Based on this new approach, enterprise systems are designed to have Business Intelligence (BI) as an umbrella concept which covers various enabler tools and capabilities in the form of non-functional requirements (Rouhani & Zare Ravasan, 2015b). Most organizations still experience a lack of business intelligence (BI) in their decision-making processes when implementing enterprise systems. The current state-of-the-art in decision support focuses on the intelligence requirements of enterprise systems as important quality aspects, along with other functional and non-functional needs. But the literature lacks studies on the evaluation of these intelligence requirements (Rouhani & Zare Ravasan, 2015a).

In this book chapter, business intelligence and enterprise systems literature are reviewed. Also based on the latest researches, the position of BI on these systems is discussed. In the following, through the study of BI capabilities and proposing them as non-functional, the BI Impacts on the design of enterprise systems and software would be described and the direction for future research and insights for information systems development would be prescribed.

BACKGROUND

In this chapter, it will be given literature review about business intelligence and enterprise systems. The lack of a large number of researchers will limit this work on newer research period.

Business Intelligence

The term Business Intelligence was introduced to describe a set of concepts and methods to improve business decision-making by using fact-based, computerized decision support systems. This term is introduced by Howard Dresner of the Gartner Group (Nylund, 1999). The first definition introduced BI as a management philosophy and tool that help organizations to manage and refine business information to make effective decisions (Gbosbal & Kim, 1986).

Business intelligence presents the process through which organizations take advantage of virtual and digital technology to collect, manage and analyze structural or non-structural data. In other words, the technology and commercial processing procedures in the decision-making are supported through the extraction, integration and analysis of data (Berson & Smith, 1997).

The purpose of business intelligence is to help control the resources and the information flows of the business which exists in and around the organization. BI makes a large contribution to the required intelligence and knowledge of the

organizations' management by identifying and processing data in order to explain their hidden meanings (Azoff & Charlesworth, 2004).

As a total definition, Lönnqvist & Pirttimäki (2006) stated that "Business intelligence as a term can be used when referring to the following concepts":

1. Related information and knowledge of the organization, which describe the business environment, the organization itself, the conditions of market, customers and competitors and economic issues;
2. A system and a systematic process by which organizations obtain, analyze and distribute the information for making decisions about business operations.

Eckerson realized that business intelligence must be in able to provide the production reporting tools, end-user query and reporting tools, on-line analytical processing (OLAP), dashboard/screen tools, data mining tools and planning and modeling tools (Eckerson, 2010).

Bose (2009) believed that the role of BI is preparing the right information to the right people at the right time to improve decision making, hence improve managerial proceeding and enterprise performance. Generally, the main focus in managerial approach is on the process of gathering data from internal and external sources and of analyzing them to produce relevant information to the decision making process (M. Ghazanfari, Jafari, & Rouhani, 2011; Petrini & Pozzebon, 2009). In technological point of view, BI has been proposed as an instrument of analysis, providing automated decision making about business conditions, sales, customer demand, product preference, and so on. It uses a different type of analysis and mathematical, statistical and artificial intelligence, as well as data mining and OLAP to take a decision in more suitable format (M. Ghazanfari, et al., 2011; Petrini & Pozzebon, 2009). Ghazanfari et al. (2011) and Rouhani et al. (2012) claimed that there is

one more approach in BI definition called system enabler in which the main focus is on value added features on supporting information.

Enterprise Systems

Enterprise systems (ES) which also called Enterprise Information Systems, have emerged as a promising tool used for integrating and extending business processes across the boundaries of business functions at both intra-organizational and inter-organizational levels in the past decade. ES provides an IT platform that enables industrial organizations to integrate and coordinate their business processes; it is considered a revolutionary advance in the continuous evolution of computer applications in business and industry (Xu, 2011). Enterprise systems as a commercial software packages, promise the integration of all the information flowing through a company, from customer information, financial and accounting information to human resource information and so on.

In the 1990s, enterprise systems have been mainly used for managing the physical assets of an enterprise but today it is known that the knowledge is a compilation of an enterprise's invisible assets (Xu, 2011). Increasing requirements for extended enterprises have also stimulated the integration of the knowledge management function into enterprise system for knowledge asset management (Xu, 2011). The concept of integration enterprise system and knowledge management becomes a strategic initiative for providing competitive advantages to enterprises. Entire Resource Planning is considered a significant step in the evolution of ES.

Types of enterprise systems include Enterprise Resource Planning (ERP), Supply Chain Management (SCM), Supplier Relationship Management (SRM) and Product Lifecycle Management (PLM). The enterprise resource planning system integrates software applications in the same way as the business processes (such as purchasing, finance, human resources and inventory manage-

ment) are integrated. Within an ERP system, the software modules may communicate and share data. Each module has few applications that perform the required functions to execute particular end-to-end business processes. ERP applications support various operational and administrative tasks. These applications may also support a number of different industries, including oil and gas, banking and so on (Rouhani & Zare Ravasan, 2015a).

BUSINESS INTELLIGENCE OF ENTERPRISE SYSTEMS

Nowadays, the individual system approach applied to decision support systems (DSS) has been substituted by a new environmental approach. In the past, decision support systems were independent systems in an organization. They had a frail relationship with other systems. However, now enterprise systems are the foundation of an organization. And practitioners design and implement business intelligence as umbrella concept creates a decision-support environment for management in enterprise systems (Alter, 2004).

The increasing trend to use intelligent tools in business systems has increased the need for BI evaluation of enterprise systems. There are some delimited efforts to evaluate BI, but always they consider BI as tools or separated systems to enterprise systems.

In the year of 2008, Elbashir et al. suggested measuring the effects of business intelligent systems on the business process and provided some effective methods for the measurement (Elbashir, Collier, & Davern, 2008). One year later Lin et al. have developed a performance assessment model for business intelligent systems using analytic network process (ANP) (Lin, Tsai, Shiang, Kuo, & Tsai, 2009). In that way, business intelligence viewed as an independent system. Ghazanfari et al. (2011) made a model for the business intelligence assessment of Enterprise Systems. Their model can be applied to assess and rank enterprise

software based on their business intelligence capabilities. Further, Rouhani et al. (2012) proposed an evaluation model of business intelligence for enterprise systems using fuzzy TOPSIS. They utilized fuzzy TOPSIS approach to rank ESs, based their BI potentials. In the same year Popovic et al. (2012) proposed the model based on relationships between maturity, information quality, analytical decision-making culture and the use of information for decision-making as significant elements of the success of BI systems. In addition, Duan, and Da Xu (2012) pointed out the challenges and opportunities to smoothly connect industrial informatics to enterprise systems.

In 2013, Işık et al. have suggested a partial least squares model in BIS success domain (Işık, Jones, & Sidorova, 2013). This model emphasizes that decision environment has influence on the relationship between BI success and BI capabilities.

An intelligent approach to the evaluation and selection of enterprise systems includes four aspects relevant to the evaluation and selection of the most suitable enterprise systems. The first aspect of the approach is a set of evaluations that are executed in order to select supporting BI software with a high intelligence level, on the basis of the criteria of BI competency and capability. The second dimension includes analysis of the functional and non-functional suitability of the options on the basis of the requirements of the organization. The third aspect of the proposed approach is the maximization of the integration and relationships of the software and systems in the enterprise. The fourth aspect of the proposed approach is a quantitative evaluation of the implementation factors of cost and time (Rouhani & Zare Ravasan, 2015a).

BI AS REQUIREMENTS

The literature that considers the evaluation of the functional and non-functional suitability of the alternative enterprise software and systems using various criteria lacks. All previous researches con-

centrated on requirement engineering and software quality. They don't cover all aspects of enterprise systems evaluation, selection and implementation. Another observation based on the review of the literature (Jadhav & Sonar, 2009) is that although the functional criteria for software selection are altered for different software packages, other criteria related to the quality, cost and benefits, vendor, hardware and software requirements, the opinions of different stakeholders about the software package, and the output characteristics of the software package are universal and can be used for evaluation of any software package.

The functional requirements are the functions of the enterprise systems that are expected by the stakeholders and end-users. Wide-ranging industry research, in-depth interviews with users and analysis of current versions of software systems are methods for exploring the functional requirements.

The non-functional requirements are features of the system that are not covered by its functional description but are related to the capability and resiliency of the system. Researchers and practitioners have developed categories for the non-functional requirements, from different viewpoints.

Jadhav and Sonar (2011) classified non-functional requirements based on ISO/IEC9126 which has been withdrawn by the ISO/IEC 25010 in 2012 on the quality, technical, vendor, output and opinion categories.

BI capabilities are not related to specific enterprise system module or function and are related to every system with different mission. Consequently BI criteria can be discussed as non functional requirements of enterprise systems.

The intelligence evaluation criteria of enterprise systems and software are the competencies and capabilities of enterprise systems in the field of decision support and BI. There is no comprehensive list of intelligence criteria. Therefore, the authors reviewed various studies about decision support and BI and used their recent research (Rouhani & Zare Ravasan, 2015b). As a contribution,

basic BI capabilities that can be included in the list of non-functional requirements of enterprise systems and should be considered in design stages are defined below:

1. **Groupware:** Groupware is a shared tool for disseminating and sharing data, information and knowledge which facilitates collaborative communication and group decision-making. Groupware is also provides required infrastructure for the team and group working such as video conferences and documentation tools in a team working environment. Groupware has been regarded as one of the required factors in achieving BI competency in working systems (Marinoni, Higgins, Hajkowicz, & Collins, 2009; Reich & Kapeliuk, 2005).
2. **Optimization Technique:** It refers to ESs capability in supporting complex arithmetic analysis either using regular techniques such as Simplex and goal programming or meta-heuristic methods and algorithms such as Artificial Neural Network (ANNs), Genetic Algorithm (GA), Ant Colony (AC), and so on (Azadivar, Truong, & Jiao, 2009; Nie, Zhang, Liu, Zheng, & Shi, 2009).
3. **Learning Technique:** It refers to ESs learning capability in making decisions on the basis of prior decisions and the capability to learn from the historical data through discovering pattern and rules in decision making process (Power & Sharda, 2007; Ranjan, 2008).
4. **Import Data:** Data integration has been considered as one of the most important infrastructural requirements in the context of decision-making capabilities of ESs which refers to the ESs capability to extract, and load required data to its database and convert it to an understandable format (Alter, 2004; Quinn, 2009).
5. **Export Data:** It refers to ESs capability in exporting data and reports to other information systems, software packages, and other

- facilities such as Personal Digital Assistants (PDAs), mobile cell phones, and so on (Shi et al., 2007).
6. **Simulation Models:** In order to cut the costs and risks of doing real tests in operational environments, organizations need facilities that enhance a simulation of the reality and analyze the potential impacts of the events and relevant risks. This capability can help decision-makers either in a decision-making process and outcomes (Quinn, 2009; Zhan, Loh, & Liu, 2009).
 7. **Visual Graphs:** It refers to ESs capability in preparing user friendly and graphical reports and even video or 3D graphics to users (Azadivar, et al., 2009; Li, Shue, & Lee, 2008).
 8. **Summarization:** It refers to ESs capability in a summarization of the information while listing the main points in a brief and also in a comprehensive manner. This capability is of more importance in reporting features of ESs (Hemsley-Brown, 2005; Power, 2008).
 9. **Backward and Forward Reasoning:** Organizations' decision makers need ESs that justify the rational and reason of the decisions proposed by the system. Such a facility can help organizations in building trust atmosphere with regard to the results suggested by the system (Evers, 2008; Gottschalk, 2006).
 10. **Knowledge Reasoning:** Knowledge is the result of high-level ESs, formed by logical rules and support inferences in decision making. The capability of inference by machine is one aspect of BI competencies of ESs. Providing reasons based on machine inference (expert systems) in organizational decision making has been considered as an important and novel characteristic in BI by scholars and practitioners (du Plessis & du Toit, 2006; Evers, 2008).
 11. **Alarms and Warnings:** It refers to ESs capability in providing alarms and warnings in pre-defined thresholds which are substantially common in large integrated ESs such as ERPs. This capability can help decision makers proactively respond to risky situations (Power, 2008; Ross, Dena, & Mahfouf, 2009; Xiaoshuan, Zetian, Wengui, Dong, & Jian, 2009).
 12. **Dashboard/Recommender:** Every organization, regarding its unique goals and business requirements, needs some sorts of Key Performance Indicators (KPIs) differ from others. This criterion indicates ES capability in providing effective and tailor-made dashboards for new cases in organizations' different hierarchical levels (Bose, 2009; Hedgebeth, 2007).
 13. **Combination of Experiments:** Tacit and explicit knowledge of human resource should be used to verify the information of ESs. The capability of acquisition and combination of managers' and employees' experiments is an important characteristic for decision support. Historically, combination of experiments in knowledge management processes is classified as a significant requirement of decision making in organizations (Ross, et al., 2009).
 14. **Environment and Situation Awareness:** It refers to ESs' capability in extracting environmental information such as technology trends, changes in rules and regularity, rivals, suppliers and customers related indicators and also situation-specific information such as the time, place, person, challenges, possibilities, and so on, to provide more accurate results (du Plessis & du Toit, 2006; Raggad, 1997).
 15. **OLAP:** Online Analytical Processing tools enable users to interactively analyze multi-dimensional data from multiple perspectives which has been regarded as one of the most important capabilities of BI systems (Berzal, Cubero, & Jiménez, 2009; Rivest et al., 2005; Shi, et al., 2007).
 16. **Data Mining Techniques:** Data mining, a brand new and interdisciplinary field of computer science is the process of discovering

new patterns from large data sets involving methods at the intersection of artificial intelligence, machine learning, statistics and database systems which is considered as one of the most important capabilities of BI in ESs (Berzal, et al., 2009; Shi, et al., 2007).

17. **Web and Email Channels:** World Wide Web (www) and the Internet have transformed the way people communicate and disseminate information. This media along with the emerging web 2.0 and semantic web has been considered as one of the main types of media for publishing organizational reports on the web and should be taken into account in BI capabilities of ESs. This criterion also encompasses the capability of automatically sending required information and reports to the pre-defined email list (Anderson, Jolly, & Fairhurst, 2007; Wen, Chen, & Pao, 2008).
18. **Mobile Channel:** Today, regarding the penetration of mobile devices in people everyday life, ESs should be empowered by mobile channel access to system functionalities and support managers by reports on their phones and handsets (Cheng, Lu, & Sheu, 2009; Power, 2008; Wen, et al., 2008).
19. **Intelligent and Multi-Agents:** Intelligent agent is an artificial agent operating in a software environment for doing pre-defined tasks which could be regarded as another BI capability of ESs. Also, some systems composed of multiple interacting intelligent agents known as a multi-agent system for doing complicated tasks (Gao & Xu, 2009).
20. **MCDM Tools:** Whether in our daily lives or in professional settings, there are typically multiple conflicting criteria that need to be assessed in making decisions. So, ESs should be enabled with Multi-Criteria Decision-making (MCDM) tools to manipulate this situation (İç & Yurdakul, 2009; Marinoni, et al., 2009).

As it is obvious above criteria or requirements are not related to specific enterprise system module

or function and are applicable in every system with different business scope and they have affect on quality of decision support services. Therefore they would be classified as non functional requirements of enterprise systems. But meeting all these non functional requirements are not mandatory and they can be meted in different level of BI maturity and development.

SOLUTIONS AND RECOMMENDATIONS

A series of methodologies and processes can be used to design and develop an enterprise system. Traditional developers have used an engineering approach such as the system development life cycle (SDLC), which is a systematic procedure of developing an information system through stages that occur in sequence. And recently many developers use Object-Oriented Analysis and Design (OOAD) for enterprise system engineering (Rumbaugh, 2003).

But in both mentioned approaches of system design, requirement engineering is critical process. This process focuses on the functional requirements and in next step selects the non functional level to deliver that functions. For as much as, the key to successful enterprise systems is an exact design, BI should be considered in selection of those non functional especially.

Based on the mentioned BI capabilities as requirements, new disciplines in the stage of requirements specification would be exist. And system designers should think more about business intelligence platform and tools and also should elaborate BI capabilities as non-functionalities of their desirable system. Requirement engineering gets new aspects and can be tailored and improved by the decision support vision in enterprise system. As current research contribution, the BI-Based design area of enterprise systems proposed in below:

- **“What Happened” Analysis:** Visual graphs, Summarization, Import data from

other systems, Export reports to other systems, OLAP, Web channel, Mobile channel, E-mail channel, Alarms and warnings.

- **“Why Happened” Analysis:** Backward and forward reasoning, Knowledge reasoning, Environmental awareness, Simulation models, Dashboard.
- **“What Next” Analysis:** Group decision-making (Groupware), Optimization technique, Learning technique, Combination of experiments, Intelligent agent, MCDM tools, Recommender.

FUTURE RESEARCH DIRECTIONS

Considering the current review and recommendation, some respectful and applicable suggestion can be presented for implication as follows: first, in every enterprise system development methodology a major step can be added for BI requirement analysis and design. Second, determination of the most needed BI non-functional requirement to reach targeted decision support benefits in enterprise systems has been clear, therefore the organizations have a roadmap to implement the right BI not in the form of independent tools but in the form of embedding requirements in enterprise systems. Third, in acquiring and selection of enterprise systems the proposed criteria would be useful as evaluation criteria.

Based on mentioned findings, it is possible to make some insightful recommendations for future research. First, it is possible to establish the requirement engineering best criteria to do list as a standard. Second, presenting a customized information system development methodology based on BI requirements. Finally, it is recommended to consider and test the effectiveness model of those BI capabilities based on ES user satisfaction data.

CONCLUSION

Business intelligence includes information and knowledge of the organization, and also system and systematic process of decision support in business context. Nowadays, BI capabilities have been transformed to the new criteria for evaluation and accusation of enterprise systems and software. In this chapter, business intelligence and enterprise system concepts were reviewed and the BI position in these system was discussed. The recent efforts show this position as innovative requirements of enterprise systems. Therefore based on this point of view, novel and modern non-functional requirements (BI capabilities) should be embedded in enterprise systems and software. For this reason, the design stage of traditional system development life cycle has the responsibility about decision support besides the functional support and should consider and elaborate the proposed BI requirements. As current research contribution, the BI-Based design area of enterprise systems should think about: “What happened analysis”, “Why happened analysis” and “What next analysis” non-functional requirements.

KEY TERMS AND DEFINITIONS

Business Intelligence: Business intelligence, or BI, is a general term that refers to a range of capability and tools used to analyze an organization's raw data and transform them to actionable knowledge by data mining, online analytical processing, querying, reporting and so on.

Enterprise System: Enterprise system (ES) is large-scale application software package that support business processes, resource management, information flows, reporting, and data analytics in complex organizations and in scale of enterprise.

Functional Requirement: Functional requirement that define specific behavior or function of system which come from business needs. The plan for implementing functional requirements is detailed in the system design.

Nonfunctional Requirements: A non-functional requirement is a system requirement that specify criteria that can be used to judge the operation of a system, rather than specific behaviors. These requirements determine the quality of the system or software. The plan for implementing non-functional requirements is detailed in the system architecture.

Requirement: A requirement is a singular documented physical and functional need that a particular design, product or process must be able to perform. It is a statement that identifies a necessary attribute, capability, characteristic, or quality of a system for it to have value and utility to a customer, organization, internal user, or other stakeholder.

System Design: Systems design is major phase of information system development and is the process of defining the architecture, components, modules, interfaces, and data for a system to satisfy specified requirements.

Deployment of Enterprise Architecture From the Activity Theory Perspective

INTRODUCTION

Enterprise architecture (EA) is defined as an integrated and holistic vision of a system's fundamental organisation, embodied in its elements (people, processes, applications, and so on), their relationships to each other and to the environment, and the principles guiding its design and evolution (Janssen & Kuk, 2006). According to Kaisler, Armour and Valivullah (2005), EA identifies the main components of the organisation, its information systems, the ways in which these components work together in order to achieve defined business objectives and the way in which the information systems support the business processes of the organisation. Kamogawa and Okada (2009) asserts that the compelling need of EA is to enable strategic business goals and organisations to derive strategic outcomes from EA in terms of operational excellence.

Organisations do admit and acknowledge the importance of service delivery to their clients and citizens respectively. However, many clients and citizens continue to be dissatisfied with the type of services that they get. In attempt to get solution, some countries opt for transformation of their governments' activities into e-governments (Janssen and Kuk 2006; Marawar, Kale and Araspure 2010; Mohamed et al, 2012). According to Lee et al, (2013) the conception of Government-wide EA is the result of e-government considerations. Notably, EA is promoted as a key tool in the

transformation and modernisation of country governments (Madsen & Heje, 2009).

The rationale for the deployment (development and implementation) of the EA may vary from one organisation to another. However, the underlying aim is to provide a better structure in order to effectively manage IT-related projects and development activities across an organisation (Janssen and Kuk, 2006). Mohamed et al. (2012) posit that reasons for EA adoption include reducing the cost of IT and business operations by identifying duplications and opportunities for reuse and enabling interoperability and providing technical and managerial standards for agencies.

In some countries, the Government-wide EA's aim is for each ministry's investments in IT to be aligned with government-wide policy goals (Lee et al., 2013). The author argues that, government Ministries experience challenges in the planning, development and implementation of their information systems and supporting technologies. Government-wide enterprise architecture is seen as the strategy to eliminate inconsistencies and duplication of efforts in information systems across government Ministries. It enables improved citizens and business relationships, where by citizens can interact with Ministries as integrated businesses (Janssen and Cresswell 2005). The objectives of this study was to presents the influencing factors in the deployment of EA in organisations. This will assist organisations including government to assess and examine how

EA could be deployed for efficiency and effectiveness in addressing the challenges of uniformity integration, of processes, systems and technologies within their organisations.

The remainder of this paper is structured into four sections. In the first section, activity theory is discussed. The second section presents analysis of EA deployment from the perspective of activity theory. The third section presents a model and discussion on the factors which influences the deployment of EA in an organisation. A conclusion is finally drawn in the last section.

BACKGROUND

Activity Theory as a Lens

This study uses Activity Theory (AT) to analyse the factors that influence the deployment of EA. The AT is a socio- technical theory that is concerned with the development of social activities. As shown in Figure 1 below, AT consists of six main components. According to Golsorkki, Rouleau, Seidl and Vaara (2010), the theory “conceptualises the on-going construction of activity as a product of activity systems comprising the subject; the community within which subject interacts with other subjects; the tools that mediate between subjects, community and objective” (p. 127). In activity theory, subject is referred to as any living being with needs. As noted by Kaptelinin and

Nardi (2006) in activity theory not every actor is a subject. According to Kaptelinin and Nardi (2006) in AT a subject have needs that can be met only by being and acting in the world. Therefore non-living actors such as cars, computers cannot be regarded as subjects. Actors use tools to pursue their goals, and perform their activities. Uden (2007) stated that tools can be physical entities, such as a hammer or psychological such as language, culture or ways of thinking.

AT is used in information systems and technology studies primarily because the development, implementation, and management of systems and technologies are regarded as social technical activities. During the development and implementation of information systems and technologies in organisations, many actors are involved. Their involvement is governed by the organisation’s rules, cultures, values, and norms. The governance is mainly to ensure and enforce commitment, focus, and order; critical aspects that are needed in order to achieve organisational goals and objectives. However, rules can come in varying degrees, and can constrain or liberate the activity of a system (Yamgata-Lynch, 2010).

Also, information systems and technologies are developed and used according to the actors’ knowledge and specialisations. AT defines specialisations as a form of division of labour. Uden (2007) stated that the divisions of labour are concerned with how tasks are divided between community members and also the division of

*Figure 1. Activity theory
Engestrom et al., 1999.*

power and status. Due to the powers that actors possess, they can enable or constrain systems and technologies' activities. AT provided a theoretical lens which was used to analyse the activities and processes of the actors in the deployment of EA.

Analysis of EA Deployments

The development and implementation of information systems and information technologies is a challenging process. In organisations, process involves IT specialists, stakeholders and business staff with diverse and often conflicting goals. The EA provides approaches and strategies to deal with such challenges. Through its various domains which include business, information, application and technical architecture, EA provides a holistic view of the Enterprise's operations, processes and activities. In general terms, EA specifies how information systems and technologies are related to the overall business processes and organisational activities. The deployment of EA enables an organisation to support, manage and govern their information systems and their supporting technologies to achieving and improving on effectiveness and efficiency. This manifests to minimising risks and inconsistencies through principles, standards and governance of technologies. Also, this addresses the challenges caused by constant changes as a result of changing environmental trends and business processes, which inevitably leads to obsolescence in IT. EA enforces change from the perspectives of the current to the future, at different levels and across its architectural domains. This change also helps to identify redundancies and address across the IS/IT infrastructures, for organisation's needs, goals and objectives.

The EA has been deployed in many different environments and in various ways in recent years. Yet, it continues to strive in the challenges it was purposefully deployed to addressing. From the perspective of AT, this section presents analysis of the underlining guide and scope within which the EA is deployed in organisations. This includes understanding the Enterprise, Organisational

Units, the effect of Change in context, the necessity of Information Systems and Technologies, and the recipients of services:

The Enterprise

The enterprise represents the bigger organisation with all the connections to the external environment which includes business partners, suppliers, debtors, stakeholders and customers. Within context, the enterprise mandates and delegates the power to manage the selection, development, implementation, support and management of processes, information systems and technologies across its business units. Its responsibility is to ensure that the required IS/IT complies with the defined ICT policies and standards, and to advice on best practices and strategies in the deployment, support and management of information systems and technologies.

As IT needs arise within individual units, the enterprise communicates them to the respective authorities within the environment. However, not every employee is satisfied with the communication channels that are used to communicate the IT needs of the organisation. Some employees sometimes do feel that management discussed matters without involving them from the very beginning. As an implication, some IS/IT artefacts that are deployed are not being supported or reluctantly by some employees in the organisation. This also results resistant towards the organisation's projects.

Within the enterprise, the selection, development and implementation of technologies involved actors from different backgrounds. Depending on the actors' roles and responsibilities, some used their political power to influence and manipulate decisions. As a result, some decisions were not made for the best interest of the whole organisation but rather to serve personal interests.

Organisational Units

The Organisational Units are defined accordance to the businesses and activities of the organisation. The most common among organisations are

Information Technology (IT) and Human Resource (HR), mainly because of their essentiality. In an attempt for an organisation to achieve its goals and objectives, the various Units adopts IT artefacts to support and enable their activities and processes. However, some of Units are often challenged with their ICT's operations in an organisation. Some challenges include the development and implementation of the supporting technologies, compatibility and integrations issues. Such challenges prohibit the Units from attaining the potential of their investment on IT.

The IT Unit takes cognisance of the operations, processes and activities of Units in providing them with support and enablement. To do this, the focal actor, which often the IT Chief Information Officer or Director must have a good understand of the Units, and have relevant skills-set under his/her auspices. In some instances, the employees specialised in more than one area. As a result, some employees belong to more than one network within the organisational Units. Their participation in the organisation's projects is therefore influenced by their involvement in other networks.

In some organisations, many actors are not aware of the underlining roles and responsibilities of the IT Unit. Some employees from the business Units indicate that IT is supposed to support their activities, irrespective of what it is including telephone and other technological artefacts. This is due to lack of communication between the units (business and IT). Also, each unit sometimes feel that they are more superior to the others. As a result there exist competitions between the units instead of working together for the interest of the organisation. EA must is expected to bridge the gap between units, using communication as one of its tools.

Information Systems and Technologies

The Units and the Enterprise at large make use of IT artefacts for various reasons, such as to collaborate and share information from person-to-person, unit-to-unit and organisation-to-organisation. Such collaborations ensure that the organisation

have real -time information that are required by employees and clients to make informed decisions.

The selection, development and implementation of EA require knowledge and skills to succeed. As such, the employees interpret and understand the technologies based on their knowledge and skills. EA skills in the many organisations are acquired through formal education or through on-the-job training. However, knowledge and expertise is a challenge, but remain an essential aspect of the deployment of EA. In an attempt to resolve this challenge, some organisations do outsource the activities of EA to other organisations. Interestingly, the challenge persists because not every activities of the EA can be outsourced due to its strategic nature. Irrespective, insiders are required in the implementation and support of those activities that are outsourced.

Also the deployment of IS/IT depends on both technical and non-technical factors for efficiency and effectiveness. However, in some units of many organisations, the technical factors are often more glorified than the non-technical factors. Thus, non-technical factors, such as organisational culture and structure need to be represented and understood in the deployment of EA in organisations. This includes the creation and communication of employees' roles and responsibilities across the structure. Depending on the organisational culture, the activities and processes are legitimised, and therefore influence the deployment of EA.

The selection, development and implementation activities and processes are guided and informed by the business rules, policies and standards. The use of standards and policies must be well understood across the IT and business units. Standards and policies enable and can also constrain uniformity and order necessary factors and activities, in achieving organisational goal and objectives.

Change

Organisational processes and activities are constantly changing. The change comes from different sources, and is caused by the internal and external

factors, such as globalisation, new markets and international laws. These changes impact the way society lives and conducts businesses. The impact can be both negative and positive, depending on how the change is handled. The organisation's survival and competitive advantage also depends on how efficient and effective it manages and responds to change, using the EA.

Information systems and technologies effectively respond to its purpose according to their life span. For example, hardware such as servers, printers and computers function effectively for a period of three to four years. Due to the fast changing technologies, organisations often find it hard to keep up with the latest technologies. As a result, most organisations are operating with obsolete technologies. The application of obsolete technologies is often a challenge and as such, the technologies are not compatible and *integratable* with others.

As activities and processes within society change, they have an impact on IS/T. As such, IS/T need to be re-engineered and re-designed to support and enable new processes and advancements in the society. Change in an environment is communicated to respective authorities. The communication is sometimes carried based on understanding and interest of the actor. This makes actors critically important in the deployment of EA.

MODEL FOR INFLUENCING FACTORS

The above analysis was carried out, using Activity Theory. Based on the analysis, some factors were found to be of significant influence in the development, implementation and management of EA within context and relevance of organisations' environments. The factors include business process, communication, lack of awareness, roles and responsibilities, actors' relationships, collaborative technology selection processes and consultant dependency, as depicted in the Model (Figure 2). The Model illustrates the relationship, interconnectivity and dependence of the factors on each other. The discussion on the factors should be read with the figure to get a better understanding on how the factors influence the deployment of EA in an organisation.

Business Process

EA is process oriented, and as such, it depends on business and IT processes in its deployment. Business processes define how the activities are executed and by who. They are used as guidelines by employees. Processes are of significance to the organisations' effective operations. How processes are communicated and interpreted by employees,

Figure 2. Factors influencing EA deployment

does impacts the deployment of EA, which manifest in IT processes. IT processes include selection, development and implementation of technologies in organisations.

Processes are defined based on the various business functions, which defines the individual business's daily operations. The operations are the activities that uniquely differentiate the business units within an organisation. Due to business functions' interdependency, processes are interconnected across the organisations. Interdependency calls for an understanding between the various business functions and processes. Not considering and a lack of understanding of business functions interdependence during the selection, development and implementation of information systems and technologies leads to process misalignments.

Communication

Communication plays a vital role in the deployment of EA, which has impact on the selection, development and implementation of information systems and technologies in an organisation. How business process, needs and technology needs are communicated to the employees impacts their involvement in the organisational activities. Communication is done according to the policies and standards defined. This ensures a governed interaction among the employees. The communication process is influenced by the organisational structure, which influence how EA is deployed in the organisation. Employees at the operational level communicate on a daily basis as they interact with each other when carrying out their tasks.

Communication can promote a positive environment where there is sharing of information and knowledge. This leads to employees' full participation in organisational activities and as a result, new and fresh ideas are brought on the table. On the other hand, a lack of communication among the employees can hinder organisations' deployment of the EA. When the organisation's processes and activities are not well communicated, employees

are reluctant to participate in the deployment of EA. Reluctance leads to conflicts and demoralisation among the employees, in the process.

Lack of Awareness

To achieve the organisation's objectives and goals through the deployment of the EA, business processes, principles and standards are essentially important, and must be communicated to the employees. However, the communication process is not always constructive and done as expected. As such, it results to lack of awareness among employees, in some cases. Due to the lack of awareness, activities are not always carried out as per defined standards, in the deployment of the EA. Awareness is impacted by information flow in the organisation.

Information flow is done from top-down, from management to operational employees as well as from bottom-up, from the operational employees to the management. Effective and efficient information flow enables rapid business decision making and information sharing. The design, development and implementation of information systems aims to establish the value and importance of using information effectively across the various units of an organisation, as well as the need to attain collaboration with customers.

Roles and Responsibilities

Employees participate in the deployment of the EA according to their roles and responsibilities. Roles and responsibilities are defined to ensure that employees carry out the tasks allocated to them. The roles and responsibilities are discussed between the employees and the management. The negotiations between the employees and management is to ensure that both parties are aware and understand what is expected of them and to resolve roles and responsibilities conflicts, in specific task, such as deployment of the EA.

Roles and responsibilities are assigned to employees in accordance to relevance factors, such as skills and knowledge. However, some employees are knowledgeable in more than one business function. As a result, there is heterogeneity of actors within organisations. Due to the heterogeneity of actors, an actor can partake in various projects relating to the development, implementation, maintenance and usage of systems and technologies. The involvement of the actors within a project leads to the creation of actors' network. In actor network theory, a network is an interconnection of both technical and non-technical actors. Actors can belong to more than one kind of network. The actors' performance in a network impacts their involvement in other networks. As such, due to the commitments, they might not fully participate in other networks.

Actor Relationship

Technical and non-technical actors depend on each other through their interaction, in the deployment of EA in their organisations. This could hold to the symmetry argument by actor network theory, which says that human and non-human actors are equal, and should be treated as such. Even though ANT has been criticised for such philosophical assumptions, the argument seems to reflect from the deployment of EA, in that humans depends on technologies and processes for EA to be deployed. Technical actors are used as tools to enable and support employees when carrying out their activities. This is to promote efficiency and effectiveness within organisations. On the other hand, the technical actors were selected, developed and maintained by the non-technical actors through the means of other technical actors. Actors' relationship is of importance for the organisations' operations. Without their interactions, it would be impossible to achieve the organisational goals and objectives.

Collaborative

Actors collaborate with each other on the basis of their relationship. The collaboration that happens between individuals or groups impacts the deployment of EA. Some of the collaborations are carried out through the means of information technology, such as email, which are subjectively read and understood. However, the use of such technology was viable and feasible from two different perspectives; to eradicate duplication and enact synchronisation, including support and the enabling of real-time data across business units.

Collaboration is crucial as business units are dependent on each other when carrying out their activities. Through collaborations, employees share ideas and resolve disagreements. This is seen as an effective way to support employees within the organisations.

Technology Selection Process

Technologies are selected according to relevance to business unit or the organisation. Also, the focal actor can decide on technology selection based on personal interest. Such process has impact on how EA is deployed in an organisation. The selection process involves actors from business and IT settings, their knowledge about business functions and information systems and technologies. This promotes understanding and collaborations between business and IT units within the organisations. The lack of cooperation between the two teams leads to conflict within the various projects. Rivalry on many issues during the selection, development and implementation process results into misalignments among business and IT processes.

The selection process needs to be controlled and managed accordingly. This is not often the case, which makes a stronger case for EA and governance. Governance helps to maintain the scope and boundaries within which employees

carry out their activities. Through governance, the principles, policies and standards are developed. Principles are guiding statements that guide employees' actions on a daily basis. Employees' interactions are done according to the defined organisational principles. Good principles lead to good professional work ethics and a collaborative working environment.

The purpose of standards is to ensure uniformity and consistency across the organisation. Process uniformity and consistency leads to ease of interaction among the employees as they are able to relate to one another about the processes in place. This ensures that the developed and implemented information systems and technologies are fit for supporting business processes. In addition, technology selection process is influenced by politics. Politics is a manifestation of actors' relationships. Because of their roles and responsibilities, employees use their power to influence the selection process. In most cases it is carried to satisfy individuals or groups' personal interests rather than the organisation's business interest.

Consultancy Dependency

Technologies selected are either developed in-house or are outsourced. The rationale for outsourcing is due to the lack of technical know-how within the organisation. Outsourcing enables organisations to acquire technological artefacts from other organisations that have the necessary skills and competencies. This allows the employees to focus and concentrate on other projects they are capable of managing.

Also, outsourcing entails the process of skills transfer by the consultants to the organisations' employees. In an attempt to acquire such skills, during the development and implementation process, employees are often involved and trained on how to use and maintain the technologies. Due to the specialised nature of information systems and technology, in most cases skills transfer does not always take place as expected. This can be due to the systems complexities, and as such there is

limited time for the employees to learn, adopt and acquire the necessary skills about the technologies.

Also the consultants feel that they are the custodians of the application hence they should be the ones responsible for applications and systems maintenance. This has a serious influence on the collaboration among the organisational employees and the consultants. As such, some actors do not fully collaborate and this negatively impacts skills and knowledge transfers within the organisation. As a result, the organisations constantly depend on the consultants for support as they are more knowledgeable about the implemented technologies.

FUTURE RESEARCH DIRECTIONS

Organisations strive to obtain value from their supporting technologies; however the management of these various technologies can be challenging. These have negative impacts on service delivery. As IT becomes part of every organisation there is a need for governance and management approaches of information systems artefacts. In doing so, the influencing factors become critically important. Deployment of strategic approaches such as EA enables organisations and governments administrations to derive values and return on investments from their technologies. Thus, EA support and enable end-to-end of processes and activities, towards actualisation of objectives. This is attainable through its various domains. EA is not a once off project as business as well as technology requirements are constantly changing. Its success depends on the organisation support and understanding of various factors.

Understanding the impacting factors is also a challenge on its own. There is need for deeper interpretation of how factors impacts each other and technologies. Thus, the activity theory was employed in the analysis, purposely to enhance our understanding of factors, which could influence the deployment of EA in an organisation.

CONCLUSION

This chapter contributes to the ineffective implementation and management of information systems, as well as lack of guidelines for defining hard and soft boundaries, the interfaces and the alignments of all components of the enterprise. As a result, organisations fail to plan and anticipate the business processes and technical innovations and this has caused IT to become a costly investment for the government. In face of these challenges, this chapter employs the lens of AT to understand and examine the activities which impacts the deployment of EA in organisations.

KEY TERMS AND DEFINITIONS

Activity Theory: A socio-technical theory concerned with human activities development and their consciousness.

Deployment: Development and implementation of Information Systems and Technologies IS/IT.

Enterprise: Represents the bigger organisation with all the connections to the external environment which includes business partners, suppliers, debtors, stakeholders and customers.

Enterprise Architecture: Systematic approach for governance of organisational artefacts.

Ministry: A legal entity operating fully under government control and is not profit driven. Used as a case in this study.

ERP Systems Benefit Realization and the Role of ERP-Enabled Application Integration

E

Joseph K. Nwankpa
Miami University, USA

INTRODUCTION

One of the key challenges facing businesses after ERP systems implementation is discerning how to realize pre-implementation benefits. ERP systems are complex software solutions that integrate information and business processes within and across functional areas of business (Davenport, 2000). These systems represent a major departure from the legacy systems and functional information systems that were widespread in the past. Some organizations have successfully implemented and benefited from their ERP system deployments (Nwankpa & Roumani, 2014) and have indeed achieved operational efficiencies and other far-reaching positive changes (Jones et al., 2008), while other organizations are left to grapple with ways to translate pre-implementation expectations into actual post-implementation benefits (Gattiker & Goodhue, 2005). Despite a large body of ERP research literature from a number of different perspectives most published research continues to struggle to adequately explain these mixed results in post-implementation outcomes and benefits (Markus et al., 2000; Nwankpa et al., 2013). As organizations continue to invest in ERP systems, the overarching question for management becomes how they can optimally realize the potential benefits from their ERP system.

ERP systems as platform technologies provide not only a common business process within the organization but also create an integrated platform that permits the adoption and integration of third party non-ERP applications (Liu et al., 2013;

Nwankpa et al., 2013). Thus, organizations with ERP systems can leverage on this information superiority and integrate additional non-ERP applications such as e-commerce applications, customer relationship management (CRM) systems and supply chain planning systems. This level of integration enabled by an ERP system can extend functionalities such as connecting a website to an ERP system as well as advancing information visibility across an organization's value chain (Nwankpa et al., 2013). For instance, integrating CRM and ERP applications can improve operational efficiencies by enabling value-chain processes to adjust promptly to each other (Liu et al., 2013). Firms with CRM applications and ERP systems are able to leverage the CRM applications' ability to extract customer information from multiple customer touch points as well as ERP systems ability to configure product offerings, scheduling, order fulfilment and interdepartmental information exchange (Liu et al., 2013). Given the critical role ERP-enabled third party application integration, studies on ERP benefits that combine ERP-enabled application integration are needed to develop a better grounded theoretical understanding and devise more effective ERP benefit realization practices.

To this end, this study sets out to examine a central research question that has not been adequately investigated in the ERP benefit literature: (i) Is there a positive implication of ERP-enabled application integration on overall ERP benefit? And if yes, what are the antecedents of ERP-enabled application integration? This study at-

tempts to answer this question by conceptually and empirically testing an integrated research model that combines the framework of ERP-enabled application integration and overall ERP benefits with survey data collected from employees in a wide range of United States firms.

The rest of the article is arranged as follows. The next section reviews the extant research on existing ERP system factors, ERP-enabled integration and ERP benefits, and based on this review the study will develop research hypotheses and propose a theoretical model. Next, a description of the research design and data collection, as well as data analyses using structural equation modeling is presented. Next, a discussion and conclusions will be presented.

BACKGROUND

ERP System Benefit

Earlier studies on ERP benefits had mixed results. Poston and Grabski (1986) used archival data to examine a group of firms before and after ERP implementation and found no post-implementation general financial improvement. However, a subsequent study found that the financial performance of non-ERP adopters actually decreased over time when compared to those of ERP adopters that remain unchanged (Hunton et al., 2003). Mabert et al. (2000) examined ERP system benefits in US manufacturing firms and found that although ERP use was pervasive in the US manufacturing sector, the system did not lead to significant operating expense reduction. On the contrary, Shang and Seddon (2002) demonstrated that the implementation of ERP systems resulted in significant operational benefits. They developed five dimensions of ERP benefits namely, operational, managerial, strategic, IT infrastructure and organizational and concluded that ERP benefit realization was in fact a continuous process with specific benefits realized at different rates in different core processes and in different organizations. O'Leary (2004) identified

tangible and intangible ERP benefits and argued that benefits vary across industries, especially intangible benefits. Gattiker and Goodhue (2005) examined ERP benefits by applying a two-phased model that delineated intermediate ERP benefits and overall ERP benefits. They operationalized and measured intermediate benefits as "task efficiency" and "coordination improvement". These benefits, they argue, will occur at the functional and operational levels within the firm but will contribute to the firm's overall ERP benefits (Gattiker & Goodhue, 2005) and concluded that realizing the intermediate benefits is critical to attaining the overall ERP benefits. Similarly, Chou and Chang (2008) decomposed these intermediate benefits in a bid to gain more insight and understanding and found that customization and organizational mechanisms are key drivers of intermediate ERP benefit while reaffirming the role of intermediate benefits as predictors of overall ERP benefit.

ERP-Enabled Application Integration

ERP-enabled application integration refers to the extent of real-time communication between an ERP system and another non-ERP application. Such integration enables an organization to increase the visibility of an ERP system by leveraging the functionalities of third party applications with the cross-functional information exchange and integration platform of an existing ERP system (Nwankpa et al., 2013). Application integration enables organizations to remain agile and responsive to their companies needs and keep pace with technological leaps and innovations. Through application integration, firms can extend and enhance functionalities, exchange information with a firm's existing ERP system and better increase visibility throughout the entire value chain (Rai et al., 2006). The extant literature has rendered some support for ERP-enabled application integration. For instance, firms adopting both an ERP system and a CRM application achieved significant improvement compared to firms adopting only an ERP system (Aral et al., 2006).

RESEARCH MODEL AND HYPOTHESES DEVELOPMENT

Building on the background literature discussed above, the following section presents the research model underlying our study in Figure 1. The reasoning for the key links in the model and the specific hypotheses are discussed below.

Task Efficiency

The degree to which task efficiency is achieved with an existing ERP system remains an important indicator of how well the system aligns with organizational goals and objectives. Thus, if management believes deploying an ERP system has led to significant gains in organizational task efficiency, they may seek to extend such benefits by integrating additional ERP-enabled applications. For instance, Liu et al. (2013) argued that real-time information sharing enabled by ERP systems led organizations to the integration of CRM applications. Thus, organizations are able to better leverage customers' information gathered by the CRM with the existing in-house information enabled by the existing ERP system. Similarly, integrating ERP systems with supply chain applications can improve operational competence by advancing information availability across an organization's value chain (Nwankpa et al., 2013). In sum, task efficiency is expected to influence overall ERP benefit and should be a strong predictor of ERP-enabled application integration as firms will seek to extend the functionalities of the ERP systems if they view the system as leading to improvement in organizational task and responsibilities. Thus, this study proposes the following hypotheses:

- H1:** For an ERP implementing firm, task efficiency will positively affect overall ERP benefit.
- H2:** For an ERP implementing firm, task efficiency will positively affect ERP-enabled application integration.

Current ERP Performance

Prior research on ERP system performance has revealed important findings for ERP implementing firms. Wei (2008) argued that to evaluate the performance of an ERP system, organizations need to first identify key performance indicators and expectations. Current ERP performance has also been linked with application integration and extension of ERP functionalities. Willis and Willis-Brown (2002) noted that the underlying ERP system needs to be stable and operating at an acceptable level of performance for third party application integration to take place. If the core ERP system is underperforming or unstable, firms may be hesitant to integrate and extend applications and functionalities as such applications rely extensively on the ERP system platform. Thus, stabilizing the core ERP system, enables organizations to successfully leverage the common database structure of the system. Such firms can extend the reach of their ERP with add-ons such as SCM, data warehouse applications and web-enabled applications (Nwankpa et al., 2013). Therefore, this study contends that current ERP performance will impact ERP-enabled application integration as organizations will view the existing ERP performance as an indicator of how well other ERP-enabled applications align with the ERP. Thus, the study proposes the following hypothesis:

- H3:** For an ERP implementing firm, current ERP performance will positively affect ERP-enabled application integration.

Extent of ERP Implementation

ERP systems have modular and divisible characteristics that create a variety of options to consider during ERP implementation. The extent of ERP implementation has come under scrutiny as researchers attempt to explain variance in ERP benefit realization (Karimi et al., 2007; Nwankpa et al., 2013). For instance, the examination of

the impact of ERP investment on market value of firms found that firms implementing ERP systems with greater functional, organizational and geographic scope had positive and higher shareholders returns while firms implementing ERP projects with lesser scope generated negative returns (Ranganathan et al., 2006). Similarly, the extent of ERP implementation has been found to influence business process outcomes. Karimi et al. (2007) noted that firms will require a certain level of depth in the initial ERP implementation to create the platform necessary to facilitate higher business process outcomes while prior research found that the extent of ERP implementation created the suitable platform for organizational ease of use of subsequent technologies (Nwankpa et al., 2013). Thus, the extent of ERP implementation this study argues will underpin how add-ons and ERP-enabled applications can be supported and integrated. This leads to the following hypothesis:

H4: For a firm that has implemented an ERP system, extent of ERP implementation will positively affect ERP-enabled application integration.

Coordination Improvement

A number of researchers have identified coordination improvement as an intermediate benefit of an ERP system (Gattiker & Goodhue, 2005; Chou & Chang, 2008). Chou and Chang (2008) found that coordination improvement was a product of organizational machinery and how well the ERP is allied with the organization. Extending the ERP system beyond the core applications can improve coordination and optimize processes for business units that deal directly with customers. For instance, integrating the ERP core with a CRM can facilitate coordination at the customer level and at the firm level as each application automatically notifies the other of customer related business processes such as customer requests, order fulfilments production scheduling and accounts and payments (Liu et al., 2013). In summary,

coordination improvement can be a predicator of ERP-enabled application integration and an indicator of how well an organization will achieve overall ERP benefit. This leads to the following hypotheses:

H5: For an ERP implementing firm, coordination improvement will positively affect ERP-enabled application integration.

H6: For an ERP implementing firm, coordination improvement will positively affect overall ERP benefit.

Impact of ERP-Enabled Application Integration on Overall ERP Benefit

Current literature suggests that platform technologies such as an ERP system enables the adoption and integration of subsequent applications and add-ons (Karimi et al., 2007; Nwankpa et al., 2013). These additional applications allow firms to extend functionalities and remain agile, strategic and responsive to changing technological opportunities. Willis and Willis-Brown (2002) argued that for organizations to realized full ERP benefits, they need to view the initial ERP implementation as a foundation laying exercise that creates the opportunity for organization to integration emerging technologies. Such a view was reinforced by Bread and Sumner (2004) who noted that the integration of CRM and e-commerce capabilities are valuable to firms due to the enabling base technology and backbone support provided by the ERP systems. Firms who do not extend the functionalities of their ERP systems or integrate their ERP systems with additional applications may not lay claims to the same overall ERP benefits (Nwankpa et al., 2013; Liu et al., 2013). These system add-ons provide very specific functionalities capable of creating a wide range of different capabilities that firms can attach to their ERP to meet and respond to emerging business challenges (Goodhue et al., 2009). Thus, this paper argues that in a post-implementation phase, ERP-enabled application integration will enable firms to achieve higher overall ERP ben-

Figure 1. Research model

efits by providing add-on solutions and specific non-critical functionalities yet necessary to meet emerging organizational needs. This leads to the following hypothesis:

H7: For an ERP implementing firm, ERP-enabled application integration will positively affect overall ERP benefit.

RESEARCH METHODS

Sample

The firm is the unit of analysis in this study as such the subjects are IT decision makers within the organization such as, the chief information officer (CIO), chief technology officer (CTO) or vice president of IT operations. These executives are typically tasked with the decisions making processes of their organizations technology needs. Dun and Bradstreet's Million Dollar database – a directory of executives was used to identify a random sample of IT executives. This database provides contact information of executives in various positions in firms in the United States and was used to identify a random sample of information systems executives holding IT positions in companies the United States. The survey instrument was developed and adapted after a thorough literature review and interviews with some IT managers. Questionnaires were mailed to

1250 corporations in the United States that were selected randomly from Dun and Bradstreet's Million Dollar database. A total of 287 responses were returned in the first mailing. Phone calls were made to about 550 randomly selected non-respondents and where possible voice mail messages were left explaining the nature of the research and requesting the contacts participation. An additional 58 usable surveys were received from a second mail providing a total of 345 responses. Out of 345 responses 317 were usable, resulting in an actual response rate of 25.3%. Table 1 provides sample characteristics.

Whenever possible, this study used previously validated measures and adapted them in the context of ERP system benefit and ERP-enabled application integration. In the absence of existing scales, theoretically grounded new scales were developed. The items for measuring the intermediate ERP benefits namely task efficiency and coordination improvements were adapted from Chou and Chang (2008) to fit the context of ERP-enabled application integration. Similarly, the items for measuring current system performance were adapted from Nwankpa et al. (2013) while the items measuring extent of ERP implementation were adapted from Karimi et al. (2007). Conversely, the three items measuring overall ERP benefit were adapted from Chou and Chang (2008). In the absence of an existing scale measuring ERP-enabled application integration, these measurement items were developed based on prior literature on ERP-

Table 1. Sample characteristics

Classification	Number of Respondents	(%) Respondents
Firm's Size (Number of Employees)

Average number of years in position	5.1 years	

enabled adoption (Nwankpa et al., 2013; Liu et al., 2013). These items were measured with multiple indicators coded on a seven-point Likert scale (See Appendix). In addition to the focal constructs, the study measured demographic characteristics of each respondent and the time elapsed since the ERP implementation.

Construct validity can be assessed using convergent validity and discriminant validity.

Convergent validity was tested using two criteria (Fornell & Larcker, 1981). First, all indicator loadings should be significant and exceed 0.7 and second, the average variance extracted (AVE) by each construct should exceed the variance due

to the measurement error for that construct. As shown in Table 2, all of the items exhibit a loading higher than 0.7 on their respective construct, and as shown in Table 3 were greater than 0.70, thus satisfying both conditions for convergent validity. The variance inflation factor (VIF) examined the existence of excessive multicollinearity among latent constructs. All VIF measures were below the 5.0 recommended minimum (Kline 1998) and the highest VIF value was 2.76. Discriminant validity was assessed using three tests. First, an examination of cross factor loadings (Table 2) indicates good discriminant validity, because the loading of each item on its assigned construct is greater than its loadings on all other constructs (Chin, 1998). Second, the correlations among the constructs are below the 0.85 threshold (Kline,

1998), suggesting discriminant validity. Third, the square root of the AVE from a construct is greater than the correlations among the construct and all other constructs in the model (Table 3) (Fornell & Larcker, 1981).

DATA ANALYSIS AND RESULT

Data analysis and empirical validation of our hypotheses were done with partial least square (PLS) analysis. PLS was selected because it enabled specification and testing of path models with latent constructs and because it places minimal restriction on the measurement scales, sample size and residual distribution (Chin & Newsted, 1999). Further, PLS allows latent constructs to be modeled as formative indicators as was the case with our data. SmartPLS 2.0 software was used for the analysis. SmartPLS 2.0 performs bootstrapping analysis to assess the statistical significance of

the loading and path coefficients (Ringle et al., 2005). Consistent with prior research using PLS models, this study analyzed the research model in two stages (Hulland, 1999; Chin, 1998). The first stage involved the assessment of the reliability and validity of the measurement model and the second stage involved the assessment of the structural model (Hulland, 1999).

Structural Model

In PLS analysis, examining the structural paths and the R-square scores of the endogenous variables assesses the explanatory power of the structural model. Figure 2 shows the results of the structural path analysis. Overall, all of the 7 paths are significant, with a p-value of less than

0.05. Hypothesis 1 received significant support. Results show that for an ERP implementing firm, task efficiency will positively affect overall ERP benefit ($\beta = 0.29$, $p < 0.05$). As indicated in

Figure 2. Research model with result

Figure 2, the influence of task efficiency, current ERP Performance, extent of ERP Implementation and coordination improvement on ERP-enabled application integration accounted for 52 percent variance of ERP-enabled application integration. Thus, providing support for Hypothesis 2 ($\beta = 0.18$, $p < 0.01$), Hypothesis 3 ($\beta = 0.21$, $p < 0.01$), Hypothesis 4 ($\beta = 0.15$, $p < 0.01$) and Hypothesis 5 ($\beta = 0.24$, $p < 0.01$). Similarly, Hypothesis 6 results indicate that coordination improvement will positively influence overall ERP benefit ($\beta = 0.22$, $p < 0.01$) while Hypothesis 7 received significant support with result showing that ERP-enabled application integration positively influenced overall ERP benefit ($\beta = 0.31$, $p < 0.01$). The model explained 61% of the variance in overall ERP benefit.

FUTURE RESEARCH DIRECTIONS

Given that respondents came from a single country, ERP benefits, national and cultural particularities need to be analyzed in future research. One suggestion, will be introducing organizational culture as a moderator in the influence of ERP benefits. Second, this study adopts a cross-sectional view in measuring the constructs. Thus, such a design may not adequately capture the interactions among the constructs and cannot establish causality. Future research might find it useful to measure these variables from multiple points in time. A more rigorous test of our model will involve a longitudinal study. Such a study may enrich the findings of our results as well as establish the causality of argument. Nonetheless, the theory in this study suggest that the relationships tested in the research model are causal in nature.

CONCLUSION

As firms continue to invest in ERP systems to integrate information and streamline business process across functional areas, it has become increasingly critical to understand how expected ERP

benefits can be attained. Drawing upon contingent resource-based theory framework and grounding our research in practitioner interviews, this study develops a more comprehensive model, which examines both antecedents and consequences of ERP-enabled application integration and extends the nomological net of constructs that examine overall ERP benefits. The results from the empirical evidence show that task efficiency, current ERP performance, extent of ERP implementation and coordination improvement positively influence ERP-enabled application integration. The study also finds that task efficiency, coordination improvement and ERP-enabled application integration are key determinants of overall ERP benefits. These results contribute to a stream of research that examines the overall ERP benefit at the post-implementation stage.

KEY TERMS AND DEFINITIONS

Coordination Improvement: The degree of real-time communication and information flow among cross-functional units within an organization.

Current ERP Performance: The degree to which the existing ERP system is able to meet the requirements of the current business functions and activities as well as anticipated future requirements.

ERP Benefit: The degree to which an ERP system improves organizational performance and objectives.

ERP Systems: Information system packages that integrate information and business processes within and across functional areas of business.

ERP-Enable Application Integration: The extent of real-time communication between an ERP system and another non-ERP application.

Extent of ERP Implementation: The degree and scale of initial ERP implementation and deployment.

Task Efficiency: The ability to achieve organizational task with minimal resources.

APPENDIX: MEASUREMENT ITEMS

Task Efficiency

1. Due to the ERP implementation, employees such as buyers, planners, and production supervisors need less time to do their job (Based on Chou & Chang, 2008).
2. ERP saves time in jobs like production, material planning and production management (Based on Chou & Chang, 2008).
3. ERP helps employees like buyers, planners, and production supervisors to be more productive (Based on Chou & Chang, 2008).

Current ERP Performance

At the time of integrating an ERP-enabled application:

1. Our ERP system performance was at a level that was considered successful (Based on Nwankpa et al., 2013).
2. Our ERP system was performing to our satisfaction (Based on Nwankpa et al., 2013).
3. Our ERP system was a success in terms of performance (Based on Kull & Narasimhan, 2010; Nwankpa et al., 2013).

Extent of ERP Implementation

1. Functional scope of implementation of your selected ERP System: Accounting/Finance, Manufacturing, Planning/Scheduling, Human Resources, Sales/Distribution, Logistics/Inventory Control, Other (please specify) (Based on Karimi et al., 2007).
2. Scope of implementation of your selected ERP: Department/Division, Multiple departments/divisions, Entire company, Multiple companies, Other (please specify) (Based on Karimi et al., 2007).
3. Geographical extent of implementation: Single site, Multiple sites, National, Global (Based on Karimi et al., 2007).

Coordination Improvement

1. ERP helps to adjust to changing conditions among different units of the firm (Based on Chou & Chang, 2008).
2. ERP has improved the coordination among different units of the firm (Based on Chou & Chang, 2008).
3. ERP facilitates the integration of important information among different units of the firm (Based on Chou & Chang, 2008).
4. ERP helps to synchronize among different units of the firm (Based on Chou & Chang, 2008).

ERP-Enabled Application Integration

At the time of integrating an ERP-enabled application:

1. Our ERP system enabled our organization to share data, communicate and implement other functional specific applications (Developed).
2. Our ERP system lead to the integration and exchange of data with other applications with specific functionalities (Developed).
3. Our ERP system enabled our firm to implement applications that go beyond the boundaries of the ERP system (Developed).
4. Our ERP system created the platform needed to integrate additional applications (Developed).

Overall ERP Benefit

1. In terms of ERP's business impacts on the organization, the ERP system has been a success (Based on Chou & Chang, 2008).
2. ERP has seriously improved the organization's overall business performance (Based on Chou & Chang, 2008).
3. ERP has had a significant positive effect on this organization (Based on Chou & Chang, 2008).

From On–Premise ERP to Cloud ERP

E**Karim Mezghani***Al Imam Mohammad Ibn Saud Islamic University (IMSIU), Saudi Arabia & University of Sfax, Tunisia*

INTRODUCTION

With the development of cloud computing, a cloud-based ERP begins to emerge as an alternative to the on-Premise solution. According to Grabski, Leech and Schmidt (2011), “Cloud computing has the potential to radically change the ERP environment. The data and the application are no longer housed on-Premise; rather, a vendor provides access to the application which can be customized to meet the user’s needs and the vendor also hosts the data securely somewhere on the Internet...Many research questions surround this evolutionary approach to ERP systems”. Arnesen (2013) adds that ERP vendors “are in the process of developing hosted or cloud solutions as the market moves to a cloud environment”. Thus, according to Mezghani (2014), “cloud ERP seems to become a real substitute to on-Premise ERP and firms would be likely “pushed” to switch toward the cloud solution”.

One of the concerns linked to ERP implementation is alignment. Indeed, ERP systems affect almost all business processes and even some strategic choices of a firm. That is why many researches focus on alignment concerns when studying ERP implementation (Hong and Kim, 2002; Yaseen, 2009; Mezghani and Mezghani, 2014). Nevertheless, as reported above, firms are more and more interested in switching toward cloud ERP (Mezghani, 2014). By the way, “their business strategy, IT strategy, business processes and information technologies shall be re-aligned” (Li, Wang, Wu, Li and Wang, 2011). Indeed, in a cloud computing environment, misalignments can lead to decreased operating efficiency and losses

for organizations (Géczy, Izumi and Hasida, 2012). However, “no cloud computing service vendor can satisfy the complete functional information system requirements of an enterprise” (Li et al., 2011). These authors add that “sometimes, enterprises have to simultaneously use software services distributed in different clouds in conjunction with their intra-IS. These bring great challenges for business–IT alignment of an enterprise in the cloud computing environment”. Also, with cloud ERP, data and applications are provider-hosted. So, the way ERP is managed may be redefined and, then, achieving alignment might be more challenging.

Thus, this chapter aims to expose the major challenges and issues linked to ERP systems alignment. Some tendencies and best practices are also proposed for firms to overcome the alignment challenges, mainly in a cloud computing environment.

BACKGROUND: ON-PREMISE ERP AND ALIGNMENT CONCERNS

Importance of Alignment When Implementing On-Premise ERP

Since the development of the Strategic Alignment model (SAM) by Henderson and Venkatraman (1993), many definitions were proposed for IT-business alignment. Based on previous studies, mainly those of Reich and Benbasat (2000), Mezghani and Mezghani (2014) proposed a definition for the ERP strategic alignment. Thus, these authors consider that such alignment exists when:

- “The ERP implementation integrates business strategy (in terms of strategic choices).
- The business strategy considers the ERP characteristics (mainly the benefits and limitations).

This alignment is defined as a pattern of co-variation due to the specificities of ERP systems that are standard and adaptable at the same time”.

Keeping ERP implementation aligned with business is an important matter because:

- **Getting ERP Benefits Depends on Alignment:** Many firms do not gain ERP benefits because they do not consider such systems when making strategic choices (Yaseen, 2009). Indeed, since ERP systems integrate all business processes, they can be considered as useful tools to access and analyze several data. Also, as ERP systems are developed based on *best practices*, firms can gain such practices if they align their business processes with the ERP ones.
- **ERP Modules Are Standard:** As mentioned below, adapting the business processes according to the ERP ones can be beneficial to firms. However, such alignment can be risky since it can affect key processes or generate resistance to change (Davenport, 1998). So, firms can choose to adapt ERP modules rather than business processes. Although useful, this alternative is also risky because it can lead to technical bugs. In all cases, project team should manage both alternatives carefully to keep alignment with low risk.
- **ERP Implementation Is a Strategic Investment:** ERP project is a costly project, time consumer and affects all business processes, so top management should consider ERP implementation as a strategic investment and priority (Grant, 2003). Besides, Lee and Myers (2004) affirm that the strategic context may change during an ERP project. Then, it is crucial to follow up continuously

the alignment state and make the required adjustments unless ERP project would face delays (Lee & Myers, 2004).

Although the importance of alignment in ERP implementation, achieving such alignment is a true challenge. That is why, several studies tried to provide ideas and practices that can be useful to realize this alignment.

Social Dimension vs. Technical Dimension for ERP Alignment

When talking about successful ERP implementation, it is necessary to focus on factors that contribute to alignment (Kidd, 2011). To achieve such alignment, the project team should focus on both ERP and business processes adaptation (Hong & Kim, 2002; Mezghani & Mezghani, 2007). However, both alternatives are risky.

When choosing a technical perspective (ERP adaptation), it is important to note that, although ERP systems are adaptable, making a deep customization can cause technical bugs and affect the integrated *best practices* (Mezghani & Mezghani, 2007). In fact, a technology-oriented project can be a key reason of failure in ERP implementation (Kidd, 2011). Indeed, ERP systems cover all business processes and are developed based on *best practices* of business management, so they should be managed as organizational projects that involve all people over the firms (Mezghani & Mezghani, 2007; Kasemsap, 2015). Then, many authors suggest focusing on business processes adaptation. Indeed, implementing an ERP can be integrated as part of a BPR (business process re-engineering) project that aims to improve business processes and align with ERP ones. Nevertheless, this alternative is very risky as it can affect the key processes and then some competitive advantages (Davenport, 1998). Employees may also resist to such adaptations mainly when organizational change is not well managed (Kasemsap, 2015)

Regarding benefits and risks of both alternatives, it is argued that alignment should be achieved

by well-defined technical and organizational adaptations with a particular attention to social concerns (Mezghani & Mezghani, 2014).

Indeed, according to the alignment duality approach developed by Reich and Benbasat (1996, 2000), many technical and intellectual tools could be used when making efforts to reach alignment. But such alignment cannot be concretized in absence of the social dimension that characterizes the interactions between IT specialists and business managers. These interactions involve communication, training, top management support, users' involvement and other social practices which let managers understand the business and technical requirements of ERP projects so adaptations could be deployed carefully (Mezghani & Mezghani, 2014). Such practices refer to management of changes (technological and organizational ones) in order to facilitate implementation and get expected benefits of ERP.

The importance of the social dimension can also be revealed when talking about skills re-

quired to ERP implementation and alignment. Indeed, in addition to IT skills, it is argued that interpersonal skills are important antecedents of alignment as they favor interactions between IT and business managers (Mezghani and Mezghani, 2014). In sum, one can understand the effects of the social dimension on ERP alignment through its components as shown in Table 1.

So, it appears that social dimension should be considered in addition to the technical one in order to achieve the required alignment when reducing the risks linked to system and processes adaptations. However, when deploying an ERP on a cloud, the required adaptations may change and then the way to consider alignment may be viewed differently.

Table 1. Social dimension and ERP alignment

Social Dimension Components	Effects on ERP Alignment	Authors
Top management support	As ERP projects involve many technical and organizational changes, the team project need to be continually supported by providing required financial and human resources to manage such changes (reduce change resistance, deploy costly customizations,...). Top managers who support ERP projects are more likely to consider such systems when making strategic choices.	(Yaseen, 2009; Silvius, De Haes and Van Grembergen, 2010; Kufandirimbwa, Hapanyengwi and Kabanda, 2012; Mezghani and Mezghani, 2014; Shatat, 2015)
Communication	Refers to information sharing among managers. It is considered as a key factor in ERP projects. Communication can promote mutual understanding between IT specialists and business ones. This helps to well adapt both ERP systems and business processes so better alignment is achieved.	(Reich and Benbasat, 2000; Kidd, 2011; Mezghani and Mezghani, 2014; Kasemsap, 2015)
Users' involvement	Involving potential users in ERP implementation helps to better identify their needs for closer alignment. Also, such involvement stimulate ERP acceptance so change resistance is reduced.	(Mezghani and Mezghani, 2007; Kidd, 2011; Kasemsap, 2015)
Training	When firms invest in training to implement an ERP system, this involves they are giving a strategic dimension to the ERP project. Users' training helps also to stimulate ERP acceptance et to prepare them for the "new" business processes (in case of processes redesign).	(Mezghani and Mezghani, 2007; Kidd, 2011; Kasemsap, 2015)
Interpersonal skills	Since ERP projects require change management practices that involve many social aspects (communication, support, involvement,...), business and IT managers need to develop interpersonal skills to well achieve such practices and to favor mutual understanding.	(Mohamed and McLaren, 2009; Mezghani and Mezghani, 2014)

ERP ALIGNMENT IN A CLOUD COMPUTING ENVIRONMENT

Cloud ERP: Definition and Overview

Cloud ERP involves using ERP on a cloud so ERP modules are got as “software as a service” (Saas). Considered as a real substitute to on-Premise ERP, “Cloud-based ERP systems are projected to cannibalize approximately 18% of the revenues of the traditional ERP market by 2016” (Das and Dayal, 2016). According to these authors, the total cost of a cloud ERP ownership can be 30%–60% less than that of an on-premise one over a 10-year period. A recent study conducted by Panorama Consulting (2016) indicates that 56% “of the respondents deploying cloud technology reported implementation cost savings of at least 20-percent”.

In fact, cloud ERP systems propose a set of benefits that make it interesting to switch toward them. Nevertheless, as cloud-based solutions, they are associated with a wide range of risks that may make managers hesitant to adopt them. From previous studies comparing cloud ERP to On-Premises ERP, Mezghani (2014) presented the main benefits and risks linked to cloud ERP implementation (Table 2).

According to Mezghani (2016), it is necessary to achieve cloud ERP alignment in order to get linked benefits. Indeed, in a cloud computing environment, misalignments can lead to decreased

operating efficiency and losses for organizations (Géczy et al., 2012). Moreover, since cloud ERP deployment involves a third party (the provider), achieving alignment becomes a real challenge.

Cloud ERP Deployment and the Alignment Challenge

As a new topic, cloud ERP alignment did not yet involve considerable studies. However, the analysis of recent studies on cloud ERP deployment reveals that such alignment is a real concern that needs to be considered and studied deeply.

When examining the determinants of cloud ERP selection and adoption, Das and Dayal (2016) developed a research model to identify the main determinants. One of the prominent conclusions made by these authors after doing empirical investigations is that “the client should examine the organizational fit of the cloud ERP in terms of technical compatibility and strategic value. If there is a mismatch, the organization will not benefit from the investment in the long run”. The authors admit that alignment is crucial for the success of cloud ERP deployment. Moreover, Das and Dayal (2016) think that firms should maintain their in-house systems if they deal with sensitive business processes or are unable to perform customizations.

In a recent exploratory study aiming at examining the alignment challenge within a firm involved in a perspective of switching toward cloud ERP,

Table 2. Benefits and risks of cloud ERP

Cloud ERP Benefits	Cloud ERP Risks
• Cloud ERP Is Cost Saver: Moving to cloud ERP reduces costs linked to licensing, maintenance and upgrading (Makkar and Meenakshi, 2012). • Cloud ERP Is Time Saver: Less time is spent in monitoring IT infrastructure. Besides, tests and trainings are conducted from the first steps of the project which can help to save time (Elragal and Elkommos, 2012). • High Scalability: According to Arnesen (2013), “you can add or reduce users as your needs change, which works especially well for seasonal businesses or companies on a high-growth path”. • Accessibility: “As a cloud based solution, cloud ERP modules can be accessed anytime and anywhere through Internet” (Mezghani, 2014).	• Security: Regarding cloud-based solutions, many managers perceive that the confidentiality and security of business data are not guaranteed (Benlian and Hess, 2011). • Internet Connectivity: “If you lose connectivity because of a natural disaster or cyber-attack or if the vendor goes out of business, you may have no access to the system or data” (Arnesen, 2013). • Dependency: “Even if choosing On-Premises ERP, firms risk to become dependent on vendors since such systems need regular maintenances and updates. This dependency seems to be greater with cloud based ERP” (Mezghani, 2014). Indeed, according to Arnesen (2013), cloud ERP vendors retain the data and firms have to pay vendors on time or they may lose data access.

Mezghani (2016) revealed a set of concerns linked to alignment.

First, the author noted that cloud ERP adoption involves a “double challenge” since adopters should care about the cloud aspect and the ERP aspect. Indeed, it is largely admitted that ERP implementation is a difficult matter. Thus, when associated to the cloud computing, such implementation becomes more challenging. By the way, cloud ERP implementation should be planned strategically in a business-IT alignment perspective (Mezghani, 2016). Moreover, “cloud computing as a new technology is involved in IT strategy. When planning IT implementation, the managers of an enterprise take cloud service as another resource apart from intra-IS. Intuitively, it enlarges the technological scope and extends the scope of IT governance. With high efficiency and flexibility, it also enhances the system competencies” (Li et al., 2011). These authors add that, from a SAM perspective, this change would have impacts on business strategy as well as business processes. According to Géczy et al. (2012), “it is important to align the organization’s functional and operating model with the cloud-based model of utilization of information technology resources and services. Misalignments lead to decreased operating efficiency and losses for organizations”.

Second, Mezghani (2016) revealed that cloud ERP adoption is also linked to technical concerns as integration with current applications and customizations. Such concerns involve alignment efforts in terms of technical fit. Indeed, “without possibilities of customization, users and organizations may encounter substantial re-training and adjustment costs” (Géczy et al., 2012). However, as customers neither own the infrastructure nor run the applications, cloud ERP may fail to give customer greater sense of ownership to make the required changes (Salleh, Teoh and Chan, 2012). Besides, cloud service provider has its general operational processes that could be adopted in most cases and provided to as many subscribers as possible but would not fit all individual requirements (Li et al., 2011). Arnesen (2013) adds that

“though configuration of cloud ERP is available to all customers, major customizations usually aren’t allowed so the vendor can maintain the upgrade path”. According to Peng (2015), “an integrated solution from one single ERP vendor may often not satisfy all business needs of companies... different cloud vendors may use very different technologies and platforms to deploy and host their ERP packages. From a technical perspective, cloud vendors may not be able or willing to customize their ERP system to allow seamless integration between the package and other cloud or on-premise applications”. Thus, it is difficult to customize a cloud ERP mainly when its components are purchased from various providers. Moreover, it is difficult to change cloud vendors even in the case of dissatisfaction (Dutta, Peng and Choudhary, 2013). Then, a weak level of alignment would favor the dependency concern considered as a crucial issue. In fact, a survey research conducted by Dutta et al. (2013) among highly experienced IT professionals involved in developing and implementing cloud based solutions showed that most of the “top ten risks” are linked to the dependency concern (difficulty to change cloud provider, privacy of data, unauthorized access to enterprise data,...). This implies that misalignment in cloud ERP deployment may not only create customization concerns but also generate dependency-linked problems. The importance of such issue is noted by Das and Dayal (2016) who stated that clients should assess the technical compatibility of cloud ERP before adoption unless they would fail in their investment.

Finally, as an enterprise system, cloud ERP requires changes within business processes. This means that firms would perform alignment efforts according to an external unit (the provider) (Mezghani, 2016). This would increase the cloud ERP risks mainly those related to privacy and provider dependency. Moreover, Das and Dayal (2016) recommend maintaining an on-Premise ERP if sensitive business processes are to be involved in a cloud ERP adoption. Also, processes adaptations may require users training to the

new practices. Dutta et al. (2013) note here that inadequate users' training on cloud services and usage could lead to resistance to technical and organizational changes.

All such ideas fit with those advanced by Li et al. (2011) who affirmed that cloud-based solutions alignment is "more complex than that of past cases". Such complexity becomes greater when cloud is not only linked to some functional software but also associated to a wide system as ERP.

SOCIAL AND TECHNICAL DIMENSIONS FOR CLOUD ERP ALIGNMENT: FUTURE RESEARCH DIRECTIONS

Regarding the alignment challenge linked to cloud ERP adoption, researchers and practitioners need to develop tools and frameworks focusing on meeting such challenge. A dual perspective based on social and technical dimensions can be proposed as an alternative for further studies.

On the one hand, integration with the existing IT architecture and customization at several levels are crucial to meet the changing demands of users and the network availability (Géczy et al., 2012). Li et al. (2011) propose a structured approach that involves mapping the processes in order to identify what they call "collaboration points" to facilitate integration of business processes into the cloud.

On the other hand, even if these adaptations may be rapidly run when adopting a cloud-based ERP, users' acceptance of such changes is not guaranteed (Salleh et al., 2012). Also, firms, especially small ones, would not have enough bargaining power to let the cloud providers customize the processes to meet one's specific requirements (Li et al., 2011). By the way, the social dimension appears as a facilitator factor as for on-Premises ERP projects mainly when cloud ERP deployment, compared to in-house one, involves a third party. In fact, according to Peng (2015), potential failure of cloud ERP should be attributed to human problems.

The possible effects of the social dimension are summarized in Table 3.

Table 3. Social dimension and cloud ERP alignment

Social Dimension Components	Effects on Cloud ERP Alignment	Authors
Top management support	"From a social perspective, prioritization of cloud ERP adoption means that such adoption is considered at the strategic level (strategic fit). In fact, given the security concerns linked to cloud computing and the possibility to integrate modules from multiple providers, cloud ERP adoption needs to be managed strategically. From an operational level, prioritization means that top management allocates the required resources for customization and organizational change".	Mezghani (2016)
Communication	Since cloud ERP adoption involves a third party (the provider), communication should be crucial to favor mutual understanding between managers and the provider and identify the alignment possibilities. Decisions about cloud adoption are complex due to the multiple challenges so regular communication between IT specialists and business managers is needed.	Katsanos (2014), Mezghani (2016)
Users' involvement	In cloud ERP projects, users' involvement is considered among the first steps that help to better identify requirements and reduce resistance to technological and organizational changes.	Makkar and Meenakshi (2012), Mezghani (2016)
Training	"The client should invest in training the employees to familiarize them with the cloud ERP application, business process modifications and change management resulting from the implementation efficiently. If managers ignore training aspects of cloud ERP, cloud ERP implementation can be inefficient"	Das and Dayal (2016)
Interpersonal skills	When to adopt cloud ERP, managers would focus more on business issues of cloud-based solutions rather than technical ones since technical adaptations would be made by the providers. The managers would need to communicate and negotiate frequently with these providers. Thus, they would need a set of interpersonal skills to be better communicators and more convincing.	Mezghani (2016)

Based on a case study conducted within a firm intending to switch toward cloud ERP, Mezghani (2016) identified many components of the social dimension in the interviewee's discourse. Terms as "discussions", "meetings", "training" and "support" are largely pronounced and linked to "organizational needs", "compatibility" and "customization". This shows that, empirically, the social dimension would play a crucial role in the alignment efforts.

Further research focusing on the social dimension components would be useful to develop more ideas about such components and propose other determinants of cloud ERP alignment. In fact, "studies on cloud-based ERP are very limited" (Peng, 2015). The existing ones focus mainly on describing benefits and risks without reflection to alignment concerns although such concerns were presented as key factors for on-Premises solutions success.

CONCLUSION

Alignment concerns have been largely considered as critical issues when talking about IT implementation. In a cloud environment, such concerns should be more problematic since cloud computing adoption involves external actors. Moreover, Parappallil, Zarvic and Thomas, (2012) state that there is an on-going trend toward studies focusing on alignment concerns linked to cloud computing due to "the enormous increase in IT outsourcing and investments in Cloud Computing services".

In this chapter, we tried to present the main alignment concerns linked first to on-Premise ERP and then cloud ERP. It was shown that, in a cloud environment, such concerns are more challenging since a third party (providers) is closely involved in cloud ERP deployment. Indeed, performing alignment efforts in this case may be hampered by the providers themselves or cause alignment to external models.

To overcome such challenges, we proposed to emphasize on a dual perspective that combines

technical efforts to social ones. Further studies may focus on the components of the social dimension as determinants of cloud ERP alignment. On the one hand, the social dimension is largely considered as enabler of on-Premise ERP alignment. On the other hand, recent studies employed such dimension as determinant of cloud ERP adoption.

Since more and more firms are pushed toward cloud ERP, conducting empirical and explanatory studies focusing on alignment concerns would be possible. Then, research frameworks could be developed toward helping practitioners overcoming such concerns.

KEY TERMS AND DEFINITIONS

Cloud ERP: Putting ERP modules on a cloud so ERP software is offered as a service. The cloud ERP is managed by the provider.

Enterprise Resources Planning (ERP): A software package that is composed of standard modules connected directly to a single database and could cover all business processes of a firm.

ERP Alignment: The coherence between the ERP requirements and the firm's ones.

Interpersonal Skills: The ability of a manager to work with a team, to understand, guide and motivate others.

On-Premise ERP: An ERP system installed locally in the firm's servers and computers. Such system is generally managed by the IT staff.

Social Dimension: Related to the interactions between the business staff and the IT specialists (IT staff and providers).

Technical Dimension: Related to all kinds of customizations and adaptations needed to operate with the ERP system.

Socio–Technical Change Perspective for ERP Implementation in Large Scale Organizations

E**Jessy Nair***PES University, India***D. Bhanusree Reddy***VIT University, India***Anand A. Samuel***VIT University, India*

INTRODUCTION

Successful implementation of an Information System (IS) is vital for sustaining and enhancing the competitive position of an organization (Gunasekaran, 2005; Jing & Qiu, 2007). Management thinking and practice reflected the trend of implementing IS by relating Information Technology (IT) based development to the strategic needs of the business to develop a competitive advantage (Galliers & Baets, 1998; Al-Mudimigh, Zairi & Al-Mashari, 2001). As computing concepts and technology advanced with time, the scope of the business systems widened to become Enterprise Resource Planning (ERP). ERP enables today's fiercely competitive business environment that requires deeper interaction between customers and organization to coordinate entire value-chain of the organization. Hence disjointed functional departments are integrated as process-oriented cross functional departments, generically known as value chain system. From technological perspective, ERP evolved from legacy systems to more flexible tiered client-server architecture and a software product that represents the final stage of an evolution towards integration, originating from IT supported manufacturing (Klaus, Rosemann & Gable, 2000). ERP facilitates in achieving greater benefits from the databases and ensures that the

system environment is built following an open system approach (Al-Mashari, 2003) enabling companies to standardize business processes with ERP system and more easily endorse best practices. By creating more efficient processes, companies can concentrate their efforts on serving their customers (Gunasekaran, 2005; Laframboise, & Reyes, 2005), maximizing profits (Laframboise, & Reyes, 2005) and reducing costs (Gunasekaran, 2005) for the organization. As ERP continues to evolve into a real-time planning tool, it will play a more strategic role in helping companies achieve their business objectives. ERP has grown from coordination of manufacturing processes to integration of enterprise-wide back-end processes and in the internet era it evolves to become the database backbone for an organization's web based front-end technology to stay connected to customers.

Organizations are yet to realize efficiencies and cost-savings as originally planned. Most organizations that are implementing ERP do not find success and struggle with ERP implementations. Meta Group reports 70 per cent failure rate of ERP implementation projects. However, adopters have not been intimidated by risks of implementation which is indicative of the boom in ERP market fueled by globalization, midmarket growth and other factors. The ERP software market reached

\$47.7 billion by 2011, a compound annual growth rate of almost 11% according to AMR Research Inc. The technical system (Lee, 2000; Lee, 1999; Bostrom & Heinen, 1977) of the organization comprising of ERP and its required infrastructure and business processes acts as an enabler in achieving the organization's strategic goals with successful implementation of ERP. ERP implementation is not only a technical system imperative but has to synergize with the social system of the organization. Lee (2004) states that as social systems seek information from technical systems, the technical systems too pose its own organization requirements on the social system. From this standpoint, ERP implementation research can be classified into two major groups where ERP deployment corresponds to a technical system and ERP organizational intervention corresponds to a social system. Though ERP implementation is highly researched, a framework illustrating all its dimensions to enable the organizational decision makers to configure the most suitable combination of variables for a research theme is lacking. The objective of this chapter is to develop a General Morphological Analysis (GMA) framework to identify and illustrate research dimensions for ERP implementation research. GMA framework is a highly structured and illustrative method to identify all possible combinations of dimensions and variables for creating models of systems and processes, which are usually non-quantifiable. Extensive literature review is carried out to categorize the dimensions and its variables of ERP implementation using GMA framework. The framework serves as a map to choose research themes on ERP implementation and a suitable configuration is formulated from the map with socio technical change as a research theme.

The following section describes ERP as the backbone of an organization's technology infrastructure by detailing the ERP evolution. In this section ERP evolution is reviewed comprehensively by drawing out the significance of an unified enterprise essential for the present competitive business environment. The definitions of ERP are

then collated through literature review to detail the evolution of ERP. The section describes the means by which ERP concept has undergone a change from technical to socio technical perspective. The next section describes a morphological field that maps out various research themes for ERP implementation. Then a particular configuration of ERP dimensions is chosen as an example of how the framework can be used by decision makers to identify themes around ERP organizational intervention. Finally, we discuss implications for future research and draw conclusions.

BACKGROUND: UNDERSTANDING THE NEED FOR A UNIFIED ENTERPRISE VIEW THROUGH ERP

Earliest legacy systems in organizations were developed to manage the transactions on a routine basis and came to be known as Transaction Processing Systems (TPS) specifically used in organization's tactical operations. The period of 1960s saw organizations centralizing their computing systems and used software packages like inventory control (IC) to automate their inventory control systems (Rashid, Hossain & Patrick, 2001). The manufacturing area focused on traditional process of management of large stocks of inventory, hence IS were specifically developed to cater to this demand. Material Requirements Planning (MRP) an earliest form of computerized IS business application is a production planning and control system for managing inventory in organizations. During 1970, MRP packages were extended with further applications in order to offer complete support for the entire production planning and control cycle (Klaus, Rosemann & Gable, 2000). The augmented version of MRP resulted in Manufacturing Requirement Planning (MRP) II which integrated traditional core functions of an organization (Yusuf & Little, 1998).

With the evolution of technology, applications were added to suit the needs of organizations which are moving away from functional

view to a process view (Al-Mashari, 2003). In the process view, organizations reorganize their structures, standardize the processes and facilitate seamless flow of information to the stakeholders by integrating the information and processes of distinct subsets of the organization (Gattiker & Goodhue, 2000). ERP emerged towards end of 1980's as a derivative of MRP and is a technology system that enables standardizing an organization's processes by integration (Shehab, Sharp, Supramaniam & Spedding, 2004). ERP includes functionalities such as human resources planning, decision support applications, regulatory control, quality, elements of supply chain management and maintenance support and the like. ERP advocates believe that it can combine business process optimization in an organization and IT solutions into one integrated solution (Chung & Snyder, 1999) and support the backend functions of the organization.

Capital intensive industries were first movers in using core modules of ERP software. With globalization, the service sectors too have realized its significance as organizations are increasingly finding it vital to keep in touch with stakeholders like suppliers, customers and partners and hence have started adding extensions to ERP in the domain of Supply Chain Management (SCM) and Customer Relationship Management (CRM). Hence ERP vendors are more focused in providing ERP systems by way of analytical applications for example SCM, CRM, Sales Force Automation (SFA), Manufacturing Execution System, Inventory Management System and so forth. This view is based on the idea that an ERP system is not simply a tool that provides a single output, but rather an infrastructure that supports capabilities of all other information tools and processes utilized by a firm (Bendoly & Schoenherr, 2005). This encompasses what is often referred to as the entire value chain of the enterprise, from prospect and customer management through order fulfilment and delivery (Shehab, Sharp, Supramaniam, & Spedding, 2004). This era of ERP systems came to be known as ERP II or the extended ERP, a

concept originally conceived by Gartner Group in 2000 and defines it as a transformation of ERP into next-generation enterprise systems. ERP II enables organization to meet customer demands through online electronic business (e-business). According to Chaffey (2007), though ERP systems were initially developed for managing the integration of processes and communication at operational level, with sophisticated solutions provided by vendors, tactical and strategic organizational levels are being integrated. Hence, ERP has become the backbone of organizations operations by connecting to the front-end operations through e-business and allowing organizations to achieve competitive advantage.

ERP systems of early era that were based on mainframe systems model moved to client/server solution model (Rao, 2000) and scalable relational database management systems (RDBMS). This has contributed to the ease of deployment of ERP systems (Gupta, 2000). New era ERP systems architecture is based on open source technology, incorporating internet in their applications for organizations to stay connected with their stakeholders since collaborating with partners is the key to success of the company. The concept of utilizing a web browser or an internet medium to access an ERP system is known as ERP on clouds. Cloud technology allows organizations to use various models to virtualize or store software, networks and communication systems and infrastructure with a vendor also known as a service provider. Though the idea seems to be favorable for business at large, the concept of implementation of ERP on cloud is still in its infancy. The evolution of ERP is depicted in Figure 1.

Once an organization (large or small and medium business) selects ERP as a technology infrastructure to be implemented, the deployment method is planned by the organization. Parr and Shanks' (2000) comprehensive literature has detailed ERP implementation approaches as comprehensive, middle road and vanilla. Koch (2007) categorizes these approaches as big bang, franchising and slam dunk respectively and defines

*Figure 1. Evolution of ERP systems
Adapted from (Nair, Reddy & Samuel, 2011).*

these concepts as follows: Big Bang method of installation is chosen by organizations when legacy systems are swapped with ERP system installed for the entire organization. This method of organizing projects requires tremendous resources from the organization in terms of investment, people and time. Adopting new standard processes and adaptation to the new software system by the entire organization has never been a success story for a majority of the organizations. In the Franchising strategy, ERP systems are independent and only common processes are linked across the organization. The merit of this category of ERP deployment is that core businesses of the organization are not affected during the course of the project since pilot installation happens at units where such a project would not disrupt the routine processes. Finally, the slam dunk method is where a few key processes are bought under the preview of the ERP system. This strategy of ERP project is adopted by small organizations which prefer to see their systems up and running and so avoid the radical reengineering of processes in the organization.

The outcome of organizational change due to ERP system intervention results in tangible and intangible benefits to the organizations. The tangible benefits from ERP implementation have a bottom-line impact on profitability by way of reduction in inventory, administrative costs, operational costs, cycle-time reduction and the like.

Intangible benefits gained through ERP system such as user satisfaction, customer satisfaction, efficient communication of information and increased efficiency in users are rather difficult to quantify. Therefore to take an extensive advantage of the tangible and intangible benefits, the technological dimension and social dimension from an organization context have to be synergetic. Table 1 consolidates benefits of ERP from the literature on the basis of dimensions such as strategic, operational, tangible, and intangible (Gattiker & Goodhue, 2000; Shang & Seddon, 2000; Murphy & Simon, 2002; Holsapple & Sena, 2003).

ERP DEFINITIONS: TECHNICAL TO SOCIOTECHNICAL CHANGE PERSPECTIVE IN LARGE SCALE ORGANIZATIONS

ERP is an application software system that unifies a large scale organization through its technology imperative by integrating island like functional departments to a cross-functional process oriented enterprise organized itself by the concept of value-chain systems. Therefore information which is a critical resource and indispensable to the organization for decision making can be leveraged by organization stakeholders seamlessly across geographical boundaries. This way ERP

Table 1. Benefits of ERP implementation

	Tangible / Quantitative	Intangible / Qualitative
Operational	○ Reduction in inventory ○ Administrative costs ○ Operational costs ○ Cycle-time reduction ○ Productivity Improvement ○ Quality improvement	○ User satisfaction ○ Efficient communication of information and coordination ○ Increased efficiency in users
Strategic	○ Process standardization ○ Process integration ○ Product Innovation ○ Cost Leadership ○ Customer Supplier Linkages	○ Customer satisfaction ○ Improved system reliability ○ Higher data quality ○ Greater agility in implementing new businesses ○ Decision making ○ Learning curve ○ Competitive Advantage

enables the organization to better deploy and manage resources and increase overall effectiveness of the organization. Davenport (1998) refers to ERP as the “most important IT development in the 1990s” accepted by the business world. Its main value is providing the opportunity to integrate the entire organization and share information through a common database repository. Table 2 describes the transformation of ERP as a concept from technology imperative to a change agent causing intervention on the organization consequently resulting in social intervention. This change from a technology imperative comprising of technology and business processes to social imperative to include dimensions such as organization and users is illustrated in Table 2. Though ERP implementation is highly researched, a framework identifying all possible combinations of dimensions and variables for creating models of ERP system implementation for evolving a research theme is lacking. This is notwithstanding Orlikowski & Baroudi (1991) state that IS research to a large extent “is concerned with the ongoing relations among information technology, individuals, and organizations (p.6)”. Nevertheless, Yusuf, Gunasekaran & Abthorpe (2004) emphasize this statement in ERP context and point that its implementation must be managed as a program

of wide-ranging organisational change initiatives rather than as a software installation effort. The following section describes a morphological field that maps out various research themes for ERP implementation.

GENERAL MORPHOLOGICAL ANALYSIS OF ERP IMPLEMENTATION IN LARGE SCALE ORGANIZATION

ERP implementation is not just an installation of software but a project where the organization has to consider various issues that are organizational and stakeholder oriented. Shehab, Sharp, Supramaniam & Spedding (2004) emphasize that organizations should adopt a strategic approach by reengineering their business processes to adapt to world class built-in ERP software functionalities developed by vendors. This will enable in bringing about “deep changes” in *de-facto* methods of doing work in the organization resulting in shake up the roles and responsibilities of important people. ERP implementation seeks to integrate different components of an organization- functional units, business processes, people (Ranganathan & Brown, 2006; Gunasekaran, 2005), technology (Ranganathan

Table 2. Evolution of ERP definition

ERP Definitions	Source
Enterprise Systems are commercial software packages that promise the seamless integration of all the information flowing through a company- financial and accounting information, human resource information, supply chain information, customer information.	(Davenport,1998)
An Enterprise Resource Planning system is a packaged business software system that allows a company to: ➤ Automate and integrate the majority of its business processes ➤ Share common data and practices across the entire enterprise ➤ Produce and access information in a real-time environment	(Deloitte Consulting, 1999)
ERP systems are about people, not processes or technology. The organization goes through major strategic transformation during this period. The management of this change for ERP implementation requires careful planning.	(Bingi, Sharma & Godla, 1999)
ERP is a phenomenon leading to a complete renewal of enterprise IT infrastructure resulting in significant consequences in economic, technical and social aspects.	(Markus & Tanis, 2000)
ERP systems are the software tools used to manage enterprise data and provide information to those who need it, when they need it.	(Gunasekaran, 2005)
ERP is more of an organizational and social aspect than technical.	(Hanafizadeh & Ravasan, 2011)
ERP imposes its own logic, best practices and structure on a company's strategy, culture, organization of departments and structure and hence pushes for and demands a huge amount of change management.	(Poti, Bhattacharyya, & Kamalanabhan, 2011)
ERP systems are defined from the perspective of stakeholder groups by the perceptions they hold in the organisation's management of the change process which accompanies the implementation.	(Williams, Williams & Morgan, 2013)

& Brown, 2006; Gunasekaran, 2005), organizational issues (Gunasekaran, 2005) and partners. The components behave as a unified whole and achieve superior firm performance (Ranganathan & Brown, 2006; Gunasekaran, 2005). ERP implementation is a significant challenge due to integration of a variety of legacy systems to ERP deployments. To facilitate the users in adopting the system efficiently and effectively due to changed and standardized processes results in a socio technical change management. Nevertheless, Keen (1981) states that many IS implementation have been successful from a technical perspective but organizational failures. To identify the themes for ERP research a General Morphological Analysis (GMA) is used. GMA is a generalized framework that can accommodate and facilitate the study of various aspects of ERP implementation in a multi-dimensional space.

GMA is a method for structuring and investigating total set of relationships contained in multidimensional, usually non-quantifiable, complex problems (Ritchey, 2006). Pioneered by Fritz Zwicky at the California Institute of Technology during the 1930s and 1940s, it relies on a constructed parameter space, linked by way of logical relationships, rather than on causal relationships and a hierarchal structure (as cited in Ritchey, 2006). The dimensions identified are placed in columns and variables of each dimension are clustered under the associated dimension in columns. This visual relationship is called as a morphological field (Ritchey, 2006) and a combination of variables from each of the dimension is called a configuration or a morphotype. Three broad steps of developing a morphological framework are: *messes*- complex and unstructured issue in hand to be studied, *problems*-here the is-

sue has a defined form therefore its dimensions and its corresponding variables are identified and represented in columns and the last level is called a *puzzle*- a well-defined and well-structured problem with a specific solution that somebody can work out (as cited in Ritchey, 2002). There have been attempted studies in areas of modelling complex socio-technical systems (Ritchey, 2002), accountability in life cycle of products and packaging introduced in the market (Ritchey, 2006), virtual organization contexts (Shekar & Ganesh, 2007) and knowledge transfer research (Kumar & Ganesh, 2009).

ERP implementation calls for socio technical change in the organization. A morphological framework can be a guidepost to identify all possible dimensions and its associated variables to formulate a *morphotype* or *puzzle* to carry out further research to reduce the risk in ERP implementation. An extensive literature survey to understand different dimensions of ERP implementation using a combination of keywords such as ERP, enterprise systems, ERP implementation, ERP project, ERP implementation framework and models was carried out. The review results are classified based on two central themes or *messes* of ERP implementation research; ERP deployment and ERP intervention as demonstrated in

Table 3 and Table 4 respectively. A representative list of variables drawn from literature are listed in columns and clustered under their respective dimensions (see Table 3 and 4). ERP deployment as detailed in the earlier section of the chapter calls for organization to plan for ERP implementation based on the size of the organization, type of module, method of deployment and implementation strategy. GMA for ERP deployment will be of scope to practitioners to develop themes for future research for effective deployment of ERP. However ERP intervention analysis (see Table 4) is a highly researched area by academics and benefits the top-management in anticipating the risks associated to ERP implementation. The dimensions of ERP intervention can be categorized as stages of ERP software implementation, theoretical perspectives, ERP frameworks and contexts.

Socio Technical Change: A Morphotype of ERP Intervention

The morphology based framework shown in Table 4 provide not only a holistic map of ERP intervention in an organization but also can be used a tool to understand and analyze different aspects of ERP interventions. This is perhaps the first attempt to use morphology based approach

Table 3. General morphological analysis map of ERP deployment

ERP Deployment			
Industry	Modules	Method of Deployment	Deployment Strategies
Large scale enterprises	Human Resources	Big Bang	On - Premise ERP Installation
	Customer Relationship Management		
	Supply Chain Management	Phased (by function or location)	Hybrid Model
	Procurement		
	Project Management		
Medium and Small scale enterprises	Financials	Modular	Cloud Model
	Sales Management		
	Sales Order Processing		
	Product Life Cycle Management	Hybrid	On-Demand/Software as a Service(SaaS)
	Business Intelligence		

Table 4. General morphological analysis map of ERP intervention

ERP Intervention			
Stages	Perspectives	Frameworks	Contexts
Chartering Phase, Project Phase, Shakedown Phase, Onward & Upward Phase	Process	De-Lone & McLean Model	Benefits & Risks
	Variance		Organizational Change
	Business-IT Alignment		
Initiation, Adoption/Adaption, Acceptance, Routinization, Infusion	Actor-Network	Balanced Scorecard	Organizational Environment
	Technology Acceptance		Stakeholders-Internal & External
Project Preparation, Business Blueprint, Realization, Final Preparation, Go Live and Support	User Acceptance	Leavitt's Diamond Model	Stakeholders-Internal & External
	Structuration		
	Socio-Technical System		

to formulate different research themes on ERP intervention in an organization. The morphological map of ERP intervention given in Table 4 has four dimensions: perspective, stages, frameworks and contexts having 3, 8, 3 and 4 variables respectively. By interconnecting different instances across the four dimensions of the framework one can come up with large number of possible notions to ERP interventions. From Table 5 it is observed that we can have $3 \times 8 \times 3 \times 4 = 288$ morphotypes as themes for research for ERP intervention. ERP implementation is a collaborative process and intervention created by the technology triggers requirements of change in the social elements of the organization (Nair, Reddy & Samuel, 2011). Hence ERP intervention cannot be perceived in isolation as a technology change but as a socio technical change in an organization.

Socio technical change is a foundational area to assess impact of ERP intervention in an organization. Social factors are characteristics of the social context of the organization (Kumar & Ganesh, 2009), while technical refers to hardware and software requirements (Whitworth, 2009) corresponding to ERP implementation. The morphological map of ERP intervention is analyzed and synergistic subthemes are highlighted in Table 5. Leavitt's (1965) diamond model is a suitable framework to analyze ERP intervention on internal organizational environment dimensions: organiza-

tion stakeholders, internal organization, processes and technology (Bostrom & Heinen, 1977; Lee, 2000; Hanafizadeh & Ravasan, 2011). The four stages of Markus & Tanis (2000) called as the emergent process model for ERP implementation consists of four stages (chartering phase, project phase, shakedown phase and onward and upward phase). This software life cycle model posits the necessary actions to be deliberated by decision makers in each phase of the ERP project where actions in each phase are mentioned *a priori* (Nair, Reddy, & Samuel, in press). The socio technical change morphotype formulated in this article having subthemes of ERP life cycle, socio technical perspective, Leavitt's diamond model and organizational change can form as a basis of future research in this area.

FUTURE RESEARCH DIRECTIONS

The scope of dimensions that can be explored by both the academicians and practitioners through morphological framework is extensive. Further refinement of the morphological framework can be taken up by using rigor in gathering literature to include top quality practitioner articles and more databases for search purposes to identify more dimensions for study. Since this framework using morphology is probably the first in area of

Table 5. A morphotype of socio technical change in the morphological field of ERP intervention

ERP Intervention			
Stages	Perspectives	Frameworks	Contexts
Chartering Phase, Project Phase, Shakedown Phase, Onward & Upward Phase	Process	De-Lone & McLean Model	Benefits & Risks
	Variance		
Initiation, Adoption/Adaption, Acceptance, Routinization, Infusion	IT Diffusion	Balanced Scorecard	Organizational Change

	Socio Technical System		

ERP implementation research; refinement of this ERP implementation morphology can be a scope of further studies. New avenues of research can be explored through dimensions such as deployment models like Software as a Service (SaaS) in cloud concept since ERP software trends are orienting towards this area and issues arising in ERP implementation in small and medium size industries.

CONCLUSION

ERP is the backbone of technology infrastructure of an organization and has evolved from a technical system to a socio technical system. ERP implementation as a technological intervention ensues organizational change. There are several studies associated to performance analysis of ERP implementation and are extensively researched. The objective of this article is to use General Morphological Analysis (GMA) framework to develop research themes to analyze the performance of ERP implementation. Hence a novel morphological analysis framework is developed in this article that can be used to formulate research concepts in ERP implementation based on perspectives,

dimensions and corresponding variables. The article identifies two morphological subfields: ERP deployment and ERP interventions for technical and social perspectives of ERP implementation respectively. To a researcher or a practitioner, the framework serves as a map to choose research themes from the morphological fields of ERP deployment and ERP interventions. Application of the morphological field is demonstrated by identifying a suitable morphotype from the map with socio technical change as the theme.

KEY TERMS AND DEFINITIONS

Enterprise Resource Planning (ERP)

System: ERP Systems are *defacto* standardized application system software that centralizes database of the organization and brings about organizational change during its implementation to achieve organization goals.

Morphological Framework: An illustrative mapping of dimensions of a problem area and clustering the sub-dimensions against the dimensions to configure the problem area for research.

Socio Technical Change Perspective: The change brought about through intervention of technology on the symbiosis of social (organization stakeholders, organization structure, policies, culture, values, norms, beliefs) and technical (business processes and technological infrastructure) dimensions of an organization.

Techno Organizational Change: The change brought about during the implementation of new technology in the organization's structure, policies, culture, values, norms and beliefs.

Value-Chain: Leveraging technology to seamlessly integrate primary functional departments of the organization to process-oriented cross-functional departments to add value by way of service to end customer.

Entrepreneurship

Current Scenario of Youth Entrepreneurship in India

E**Neeta Baporikar***Namibia University of Science and Technology, Namibia & University of Pune, India*

INTRODUCTION

Many young people cannot find employment. This has become particularly acute since the education explosion in early 2000's and onset of the financial crisis in 2008. These outcomes are both inefficient and inequitable. Evidence shows that the unemployed are unhappier, more likely to experience a range of health issues, and face difficulties in integrating back into the labour market place (Bell & Blanchflower, 2009). For young people, the effects of unemployment may be particularly scarring. Evidence suggests that a spell of youth unemployment increases the likelihood of poorer wages and unemployment in later life (Blanchflower & Oswald, 1998). Such outcomes also have pronounced social costs. It represents a loss of potential output and leads to increased costs to the taxpayer apart from causing social disruptions. One potential way of integrating young people into the global economy is to increase youth entrepreneurship. World Bank estimates that by 2015, there will be about 3 billion youths less than 25 years old and a big portion of that will be in India. Hence, promoting youth entrepreneurship will not only help in reducing unemployment but more importantly show young people that they have alternatives to create their own destiny? Moreover, youth entrepreneurship has become a topic of interest for research scholars and also a subject of major concern for the Government. While youth entrepreneurship is an under-explored field, the main factor for its growing attention is the increased number of unemployed young people. Furthermore entrepreneurship is seen as

a channel for the talents of many highly educated young people to explore their potential and cash their business acumen. The core of this chapter is to provide a contemporary perspective on youth entrepreneurship.

BACKGROUND

In spite of the increasing recognition of entrepreneurship as a source of job creation, regional development, and economic dynamism in a rapidly globalizing world, there has been no systematic attempt to look at it from a youth angle. According to Holland's (1997) theory, people are attracted to work environments that conform to their personality orientation. Chell (2008) suggests that personality traits of entrepreneurs may be important for entrepreneurship. Shepherd et al., (2009) posit that the personality traits of the entrepreneur may explain entrepreneurial failure. According to Splaver (1977) it is important for you to have a good understanding of yourself and your personality, if you are to make intelligent career plans. (Ciavarella et al., 2004; Zhao et al., 2010) points out that personality trait have a direct effect on entrepreneurial performance measures. Personality traits of entrepreneurs may have a different effect on firm performance in case the firms are innovative (Zhao et al., 2010). Penrose (1959) emphasized that carrying out similar tasks has important implications for cognitive processes of human beings. Simon's (1947) gave the idea of bounded rationality which refers to human limitation to process information. Under the as-

sumption of bounded rationality, therefore, past experience influences the processing of incoming information. Witt (2000) explained that events in the environment are only perceived and interpreted along some specific associative lines. In this sense, a cognitive frame is a schematic representation of an individual's perception of the environment built through prior learning and adaptation. Gardner (1983) argues that intelligence refers to both the personal decisions and potentials of individuals. This potential comes out or develops according to cultural environment, values and opportunities. Baum et al. (2001) reported a positive relationship between practical intelligence and entrepreneurial processes and entrepreneurial characteristics, which proposes that practical intelligence is one of the strengths underlying high performance enterprises.

Although youth may not seem like a likely group for entrepreneurship because of their inexperience and lack of finances, they may not have an interest in entrepreneurship. Even if they have, intention is one thing, action is another. The proportion of youth involved in self-employment varies across countries, which may indicate variations in barriers and opportunities and labour market conditions. Societal outlook towards youth entrepreneurship is also a deciding factor. In some parts of India, where the youth comes from business families background then the motivation levels as well as support is high as compared to youth from other background. While young and adult entrepreneurs tend to have similar motivations for entrepreneurial activities, they often have different approaches and run different types of businesses. As observed, young entrepreneurs generally operate smaller businesses than adults. Youth-operated businesses are also more likely to be concentrated in certain industries with low barriers to entry and low capital requirements such as construction, information and communication and other services firms and tend to focus on narrow product lines. Accordingly, many young entrepreneurs focus exclusively on local markets because of familiarity and because they lack the

knowledge about opportunities in other markets and how to take advantage of them (Chigunta, 2002). However, at the same time, they are likely to be more open than adult entrepreneurs to international activity. Through grounded theory, review of policy documents and secondary data analysis the aim of this chapter is to provide a contemporary perspective on youth entrepreneurship with focus on India. Moreover, capacity of the ecosystem to promote innovation derives from its diversity of talents, trust across social barriers, motivations that rise above short term rationality, and social norms that promote rapid, "promiscuous" collaboration and experimentation among individuals (Hwang & Horowitz 2012). Indian entrepreneurship development shows that this distinct social behavior is highly present in the Indian ecosystem. (Baporikar, 2013)

Understanding Youth Entrepreneurship

Before looking at the potential benefits of promoting youth entrepreneurship, it is important to have an understanding of what 'youth entrepreneurship' is. 'Youth' is defined by the United Nations as those between 15-24 years of age. 'Entrepreneurship' is a generic term that subsumes many issues. It has, therefore, been defined in very many ways. Rabboir (1995) – quoted in Schnurr and Newing (1997) - lists twenty definitions of 'entrepreneurship' from various authorities on the subject. He concludes that efforts to reach a consensus on the subject have not been successful and various analysts are changing their definitions as work, study and experience in the field evolve. Given the elusive definition of entrepreneurship, it is increasingly recognised that what is of great consequence is not what 'entrepreneurship' is or who 'entrepreneurs' are, but rather what they do or the ways in which different types of people, at different stages in the lives of their enterprises will respond to assistance of various types (Schnurr & Newing, 1997; Harper, 1996). Drawing upon the above definition of entrepreneurship, and for

the purpose of hereto, 'youth entrepreneurship' is defined as the "practical application of enterprising qualities, such as initiative, innovation, creativity, and risk-taking into the work environment (either in self-employment or employment in small start-up firms), using the appropriate skills necessary for success in that environment and culture" (Schnurr & Newing, 1997). This definition assumes the following: young individuals developing and making full use of their own abilities, alone or in groups; young people defining their own problems, identifying solutions and finding resources to realize their vision; and young people realizing their own potential and vision, growing in confidence and taking active roles in their own communities.

Youth Entrepreneurship and Self-Employment

It is now widely accepted that there are many good reasons to promote entrepreneurship among young people. While caution should be exercised so that entrepreneurship is not seen as a 'mass' or wide-ranging solution which can cure all society's social ills, as many experts such as Curtain (2000) warn, it has a number of potential benefits. An obvious, and perhaps significant one, is that it creates employment for the young person who owns the business. This is especially the case in an economy subject to rationalization, change and restructuring. Many experts believe that this could bring back the alienated and marginalized youth into the economic mainstream (Curtain, 2000; White & Kenyon, 2000). There may also be a direct effect on employment if new young entrepreneurs hire fellow youths from the 'dole' queues (Curtain, 2000). In this way, entrepreneurship could help address some of the socio-psychological problems and delinquency that arise from joblessness. Youth-run enterprises (YREs) also provide valuable goods and services to society, especially the local community (OECD, 2001). Stone, et al. (n.d) in a survey of YREs in Minnesota, USA, observed that they build houses, publish books,

run restaurants, staff child care centres, provide business services, and offer others services and goods. This results in the revitalization of the local community.

It has also been observed that new small firms tend to raise the degree of competition in the product market, thereby bringing gains to consumers (Curtain, 2000). In addition, the enterprises may create linkages between youth entrepreneurs and other economic actors, such as through subcontracting, franchising, and so on (White and Kenyon, 2000). Youth entrepreneurship also promotes innovation and resilience as it encourages young people to find new solutions, ideas and ways of doing things through experience-based learning (OECD, 2001; White and Kenyon, 2000). In certain circumstances, young entrepreneurs may be particularly responsive to new economic opportunities and trends. This is especially important given the on-going globalization process. It is increasingly accepted that youth entrepreneurs can present alternatives to the organization of work, the transfer of technology, and a new perspective to the market (White & Kenyon, 2000).

In a broader sense, 'entrepreneurship', when treated as 'enterprise', helps young women and men develop new skills and experiences that can be applied to many other challenges in life. In the Oxford Thesaurus, 'enterprise' is defined as "resourcefulness, initiative, drive, imagination, enthusiasm, zest, dash, ambition, energy, energy, vitality, boldness, daring, audacity, courage, get up and go..." It is worth noting that these attributes are generally associated with youth. In that sense, youth have "the qualities of resourcefulness, initiative, drive, imagination, enthusiasm, zest, dash, ambition, energy, boldness, audacity, courage..." (Schnurr & Newing, 1997:2)

Bennell (2000) in this regard argues that the challenge for governments, NGOs and international bodies seeking to improve youth livelihoods is to "tap into the dynamism of young people and build on their strong spirit of risk-taking". Moreover, the success of the 'new economy'-however defined-is dependent on the promotion

of a culture of entrepreneurship. It has been observed that youth have the capacity to understand it and be its pioneers. This is reflected in high youth participation in internet business start-ups (OECD, 2001; Curtain, 2000). Given this situation, the promotion of youth enterprise in general and youth entrepreneurship in particular is vital. The importance of this promotion should also be seen in the context of improving social attitudes towards entrepreneurship. Collectively, these influences are referred to as an enterprise culture. White and Kenyon (2000) define an 'enterprise culture' as a "set of attitudes, values and beliefs operating within a particular community or environment that lead to both 'enterprising' behaviour and aspiration towards self-employment" (p.18).

Blockades to Youth Entrepreneurship

A lot of constraints and barriers to youth entrepreneurship have been identified like lack of capital, poor infrastructure, strict and cumbersome Government regulations, social attitudes, lack of skills, inadequate entrepreneurship education, lack of work experience, under capitalization, lack of networks, market barriers, lack of guidance and awareness etc. These constraint or barriers prevents some from turning ideas into projects. Apart from these the other barriers could be the culture, milieu, upbringing, gender bias, risk aversion and the individual persona.

Steps to Overcome Barriers

Entrepreneurship can play a role in supporting employment creation and reducing the pressures on labour market is now a well-established fact. However, there are no quick fixes to ensure that all youth are integrated into the labour market. While some countries do a better job than others, all countries face pressures and challenges in helping their youth. Yet, in Indian scenario there is a greater need to: Conduct competitions and youth fairs/melas, Develop entrepreneurship

skills, Develop entrepreneurship infrastructure, Equipping with life skills, Foster entrepreneurial mindset, Institutional Development, Investment Services, Knowledge Management, Provide information, advice, coaching and mentoring and Provide financial support.

SOLUTIONS AND RECOMMENDATIONS

There is need to stimulate policy debate on the factors that encourage youth entrepreneurship. The obstacles that stand in the and the policy measures that can support youth entrepreneurship needs to be revisited to suit the changing times and that too keep in in mind the contextual and geographical country based requirements. In general the critical issues that need be addressed immediately include: access to micro-credit for young, as a major constraint to the growth of youth enterprises is lack of access to finance. Further, lack of sufficient collateral, experience and biases further disadvantage young people. It is also important to note that many micro-credit schemes, especially youth credit schemes, have failed in many countries. The overall message from the failure of these schemes suggests that success or failure in terms of financial viability and servicing the poor, in this case young people largely depends on the design of the programme (Curtain, 2000).

To overcome the lacuna regarding micro financing the need is to treat youth as 'clients' and not mere programme 'beneficiaries', shift the focus from 'product-centered' to 'customer-based' programmes, adopt innovative approaches for security, collateral, business plan evaluation, etc., and strengthen financial systems management is required.

The second is the establishment of training and business development services through integrated approach by skills training, business counseling, and mentor support, access to working space, business expansion support, and creating support

networks. The training should also be extended to service providers in order to improve their professional and technical competence, especially in the areas of programme conception, design, implementation and evaluation. Appropriate and suitable training models need to be adopted.

Moreover, in those countries currently lacking explicit policies on youth, there is urgent need to design compressive national youth policies that indicate the directions a country intends giving to the development of its young people. Significantly, such policies should be properly integrated with key macro and sectoral policies in order to avoid treating youth livelihoods and entrepreneurship as an isolated activity. This has to be done in conjunction with intermediary and support institutions as it has radical implications. Depending on context, there is need to clearly redefining the role(s) of: Government, NGOs, Private Sector, Donor Agencies and Local Community

FUTURE RESEARCH DIRECTIONS

For effective advancement of youth entrepreneurship there are many critical components. Particularly in LDCs, there is also urgent need for a prioritization of scarce resources. While the general view is that poor countries lack sufficient resources to invest in the promotion of youth enterprise development, a review of the literature suggests that even that which is available is not properly used due to lack of priorities and strong accountability mechanisms. There is also very little research on the qualities and particular needs of youth who want to become self-employed in both developed and developing countries. Especially in developing countries, there is currently a dearth of empirical data on the informal sector, and on the participation of youth in the sector and the extent to which the existing policy and institutional framework impacts on youth entrepreneurship. So there is urgency to undertake evaluative studies on the youth enterprise development process, Tracer studies of entrepreneur training programmes,

institutional development needs, diagnosis of a variety of institutions in the public and private sectors, need to be embarked on. Research to identifying opportunities for youth in value chains and high value markets, is another interesting area for further research.

CONCLUSION

Indian is poised for growth, but its success depends on its ability to develop the skills and talents of its greatest asset: young people. Every year, millions of youth become potential entrepreneurs, yet the field—like any other field—is challenged to get people whose skills match its needs. Youth entrepreneurship is also not a panacea for solving the youth unemployment problem but it does have a role to play in facilitating both - employment and entrepreneurship development, hence it can be a part of the response. While context clearly matters, to maximize effectiveness and efficiency, policy should target resources on young people with the best chance of success, provide sufficient support to allow them to start businesses outside the low entry barrier but high competition sectors, and provide integrated packages of complementary support rather than one-shot instruments.

Increasingly, educators and scholarly work finds that for young people to succeed in today's rapidly changing and globalized world, they need an educational foundation that includes more than just academic and technical skills (Baporikar, 2014). Youth critically need life and employability skills as a way to prepare them to be motivated and confident decision-makers who can overcome adversity and realize their potential. Various stakeholders across cross-section indicate that the following core life skills are essential for all entrepreneurs especially youth entrepreneurs to possess, regardless of their enterprise size, location and responsibility level: self-confidence, ability to manage emotions, personal responsibility, respecting self and others, cooperation and teamwork, communication and interpersonal skills,

creative thinking, critical thinking and problem solving, decision-making, conflict management. These can be termed as critical success factors for youth entrepreneurship (Baporikar, 2016, 2017). If policies and programmes for youth entrepreneurship can bring scope and scale to bear on the youth employment challenge, it can fulfill its own needs for an economic development, equity while empowering young people around the world to acquire the means and achieve the stability they need to enter adulthood with renewed hope for a bright future.

KEY TERMS AND DEFINITIONS

Critical Success Factors (CSFs): CSF is greatest possible important circumstance, fact, or influence that contributes for the correct or

desired result of an attempt and it is one of the parts that make up a whole or the one that actively contributes to the production of a result or success or failure of something that is aimed to be achieved or attained.

Government: The organization, machinery, or agency through which a political unit exercises authority and performs functions and which is usually classified according to the distribution of power within it. It is a political system by which a body of people is administered and regulated.

Information Technology: The study or use of systems (especially computers and telecommunications) for storing, retrieving, and sending information.

Initiative: Readiness to engage in daring or difficult activity, the condition of being initiated into some experience or sphere of activity: knowledgeableness.

Knowledge: The fact or condition of knowing something with familiarity gained through experience or association, acquaintance with or understanding of a science, art, or technique, the range of one's information or understanding, the circumstance or condition of apprehending truth or fact through reasoning or the fact or condition of having information or of being learned.

Management: The act or activity or process of looking after and making decisions about something.

Models: An exact representation of something in greatly reduced size for better understanding and adoption if found suitable.

Opportunity: A favorable combination of circumstances, time, and place.

Policies: The science and art of employing, a careful plan or method, the art of devising or employing plans or stratagems toward a goal, an adaptation or complex of adaptations (as of behaviour, metabolism, or structure) that serves or appears to serve an important function in achieving evolutionary success.

Process: A natural phenomenon marked by gradual changes that lead toward a particular result, a natural progressively continuing operation or

development marked by a series of gradual changes that succeed one another in a relatively fixed way and lead toward a particular result or end.

Risk: To take a chance on a possible course of action to achieve a desired result.

Stakeholder: A person with an interest or concern in something, especially a business. Stakeholder is a member of a type of organization or system in which as a member or participant seen as having an interest in its success.

E

Entrepreneurship

Mehmet Eymen Eryilmaz
Uludağ University, Turkey

INTRODUCTION

From the past to today, it has been discussed by scholars of various study of fields (for example in strategic management (Barney, 2002; Booth, 1998; Eryilmaz, 2016), in organization theory (Davis & Marquis, 2005) and in business history (Kurt, 2016)) that whether the field is transformed into an academic discipline or not. In a similar vein, some early (e.g. Vesper, 1988) and recent (e.g. George & Wadhwani, 2006; Urban, 2010) studies in the field asserted that entrepreneurship gained status of an academic discipline.¹ During this study, historical background of entrepreneurship discipline will be examined. Then, some discussions and empirical studies on antecedents and consequences of entrepreneurship will be shared with readers. The study will continue with a section that focuses on the link between entrepreneurship and information and communication technologies. Then, the study will give some information on recent developments and possible future trends in the field. Finally, the study will be ended with a conclusion part.

BACKGROUND

A Brief History of Entrepreneurship and Some Definitions

According to some studies (e.g. Stevenson & Jarillo, 1990), the word of entrepreneurship was invented by an Irish-French economists, *Richard Cantillon* (1680-1734). Cantillon derived the concept of “entrepreneur” from French “entreprendre” which may be translated into English as “to undertake” (Matlay, 2005). Besides, Cantillon who

was named by Jevon as “The Cradle of Political Economy” (Hayek, 2005) stated that entrepreneurial activity includes buying from a certain price and the risk that is relating to selling from an uncertain price. In addition, the French economist *Jean Baptiste Say* (1767-1832) extended definition of Cantillon by adding the statement of “bringing factors of production together” (Stevenson & Jarillo, 1990). Another important contributor to the field, English political economist and philosopher, *John Stuart Mill* (1806-1873) asserted that main element that differentiates an entrepreneur from a manager is bearing of risk (Carland *et al.*, 1984). As consistent with this stream, Gartner (1989: 62) conceptualizes entrepreneurship as “the creation of new organizations”. In addition, *Francis Amasa Walker* (1840-1897), an American economist and educator, was another contributor to the field of entrepreneurship. According to him, an entrepreneur was a person who is born with above average talent with respect to organization and coordination of factors of production. According to him, investor who supplies needed funds and receives an interest from uses of them, and entrepreneur who obtains profit from his/her managerial capabilities, are different concepts (Balachandran & Sakthivelan, 2013).

An Austrian-born American economist, *Joseph Alois Schumpeter* (1883-1950), also brought a breath of fresh air into the field. Schumpeter conceptualizes entrepreneurs and entrepreneurship as change agents in an economy (Jones & Wadhwani, 2006) and as a situation respectively that economy totally improves. According to him, there is innovation in the heart of concept of entrepreneurship. In addition, Schumpeter defines enterprise as making new combinations. As a natural consequence of this definition, entrepreneur is

DOI: 10.4018/978-1-5225-2255-3.ch262

the person who creates these new combinations. At this point, he seemed to feel a need to explain the concept of “new combination”. In term of his idea, there can be various new combinations such as 1) putting a new good or service on market, 2) using a new method of production, 3) entering into a new market that doesn’t have information about the good, 4) finding a new source of input (e.g. raw material/half manufactured goods) and finally, 5) changing structure of market by creating or breaking a monopoly in market (or industrial reorganization). For example, in the previous year, a company announced that it will launch to produce electricity from bamboo in Japan (Milliyet, 2015). This development may be accepted as an example of entrepreneurship in a Schumpeterian manner. Schumpeterian stance differentiates business man and entrepreneur from each other (Carland *et al.*, 1984; Stevenson & Jarillo, 1990).

In 1985, an American entrepreneur, *Gifford Pinchot III* (1942 -) coined the concept of “intrapreneurship”. “Intrapreneurship can be defined as the development, within a large corporation, of internal markets and relatively small autonomous or semiautonomous business units that produce products, services, or technologies by employing the firm’s resources in a unique way” (Dollinger, 2008: 384 cited from Hisrich *et al.*, 1985).

As it can be seen above, there are two main-streams in conceptualizations of entrepreneur and entrepreneurship. The first stream strongly links entrepreneurship with behavior of risk taking. In addition, the second stream that Schumpeter takes the lead principally underlines innovative behavior of entrepreneur. There are also some eclectic approaches in the literature that endeavor to combine these two approaches as well. For example, Johnson (2001: 137) defines entrepreneur as “an individual who takes agency and initiative; who assumes responsibility and ownership for making things happen; is both open to and able to create novelty; who manages the risks attached to the process; and who has the persistence to see things through to some identified end-point, even when faced with obstacles and difficulties”. In

a similar manner, for Shane and Venkataraman (2000), entrepreneurship may associate with both new and extant organizations. According to the author of the study, since behaviors of risk taking and innovation are associated with each other and complimentary, a combination of these two streams to conceptualize entrepreneurship seems to be more appropriate. Almost every innovation trial bears a risk. For example, pen phone of Siemens seems to attract less attention than expected.

Antecedents and Consequences of Entrepreneurial Behavior

It seems that there are many triggers of entrepreneurial intent and causes of entrepreneurial success and failure at macro and micro levels. Although it is sometimes criticized by some scholars; some macro level factors such as culture, religion, trust, financial and educational systems, political and legal institutions may have some impacts on entrepreneurship processes (De Clercq *et al.*, 2013; Gohman, 2012; Jones & Wadhwani, 2006; Valdez & Richardson, 2013). For example, De Clercq *et al.* (2013) hypothesized that the relationship between two variables such as individual resources (e.g. human, social and financial capital) and new business activity is moderated by formal institutions (educational and financial systems) and informal institutions (culture and trust). Their findings showed that the hypotheses are partially supported. In a similar vein, according to Hefner, success in business of overseas Chinese may be explained by traditionally strong ties among members of Chinese families and necessity of being successful as a minority group. In a similar manner, Walker showed us in her study that how slavery and institutionalized racism in US before civil war limited entrepreneurial opportunities of African Americans. The same study also indicated that African Americans performed some entrepreneurial activities to delegitimize these institutions (Jones & Wadhwani, 2006 cited from Hefner, 1998 & Walker, 1986). In a similar vein, Turkey is 51st and 56th in “2015-2016 The Global Competitive-

ness Index” and innovation and sophistication factors subbranch of it respectively (Sala-i Martin *et al.*, 2015). According to the author, one of the most important factors for this relative failure in innovation and entrepreneurship is some problems in higher education system.

On the other hand, another stream that mainly takes support from the field of psychology investigates the relationship between micro factors such as personality traits², gender etc. and entrepreneurial intentions and success/failure (Stevenson & Jarillo, 1990). For example, Rauch and Frese (2007) found a positive and significant relationship between entrepreneurial behavior and some personality traits such as generalized self-efficacy, innovativeness, need for achievement, need for autonomy, proactive personality and stress tolerance. In a similar vein, Engelen *et al.* (2015) investigated the relationship between overconfidence of chief executive officer (CEO) and orientation of entrepreneurship and they found a positive relationship that is moderated by market dynamism. Some studies criticize the approach of personality traits to entrepreneurship. According to Gartner (1989), there aren't significant personality differences between entrepreneurs and non-entrepreneurs. Therefore, the correct question isn't “who is an entrepreneur?” to reveal entrepreneurs. Instead, the behavioral stance to entrepreneurship recommends that the question of “what does an entrepreneur do?” should be asked. On the other hand, a meta-analytic research on links between personality traits and entrepreneurial behaviors showed that personality of entrepreneurs is important. Some previous studies couldn't find a direct relationship between personality traits and entrepreneurial intent, behavior or success since some variables mediate to this relationship (Rauch & Frese, 2006). Finally, family environment and child rearing style of a parent (even toys that are given to a child) may affect future success of a child in entrepreneurship as well. For example, in many countries, majority of parents often have an interfering style in their relationships with their children. This style may affect decision making

skills and future entrepreneurial capacity of children in a negative direction.

One group of factor without another one seems to be inadequate. For example, if only macro factors were enough to understand entrepreneurship, how would we explain success differences in processes of entrepreneurship of people who live in same conditions?. However, entrepreneurial behavior in some countries that is supported by some macro level factors is stronger. Therefore, a combined set of factors (macro and micro levels) may be the best alternative to examine and explain entrepreneurial intents and behaviors (Rasmussen & Sorheim, 2006).

Again, entrepreneurial behaviors may have consequences at macro and micro levels. For example, Schumpeter claimed that entrepreneurial activity is the essence of economical development of a country (Carland *et al.*, 1984; Shane & Venkataraman, 2000). In a similar vein, some scholars discuss or empirically support the impact of entrepreneurial activities on competitive advantage of a country (Matlay, 2005). In addition, it may be expected that entrepreneurs may trigger productivity at national level by augmenting competition (van Stel *et al.*, 2005). Finally, various studies assume and empirically support that activities of entrepreneurship have some links with regional and local economic development as well (e.g. Baptista *et al.*, 2005; Malecki, 1993; Rasmussen & Sorheim, 2006). At a micro level, one of the possible consequences of a successful entrepreneurial activity is personal accumulation of wealth.³ Indeed, wealth accumulation is used in academic research as an indicator of entrepreneurial success (Jones & Wadhvani, 2006). Naturally, entrepreneurial behaviors may generate good or bad personal reputation for their owners.

Information and Communication Technologies and Entrepreneurship

“Information and Communication Technologies (ICT)” can be defined as ‘electronic means of capturing, processing, storing, and communicating

information” (Heeks, 1999: 3). ICTs may be input, output or a part of entrepreneurship processes. As an input, ICT may be used to increase entrepreneurial competencies. For example, Sinkovics *et al.* (2004) suggest that candidates of entrepreneurship need three different competencies such as intra-personal, inter-personal and organizational competencies to be successful. Some ICT tools such as mobile phones, internet discussion groups, video conferencing and computer simulations can enable competencies to be gained by students. According to Sinkovics *et al.* (2004), uses of ICT tools in international entrepreneurship education provide some benefits to students such as being familiar to values of counterparts in other countries and being familiar to new ICT tools. In addition, ICTs can create new business areas for entrepreneurs. For example, one of the newest concepts associated with ICT is “nomophobia”. According to a definition, “nomophobia is the modern fear of being unable to communicate through a mobile phone (MP) or the internet” (Yıldırım, 2014: 8 cited from King *et al.*, 2014: 28). Some health centers were founded in United States to treat addiction of people to mobile phones (Karahasan, 2012).

In addition, ICTs may be a part of entrepreneurial process (or production technology). Extant entrepreneurs can access data and information by ICT that they need to increase their performance. For example, a foreign entrepreneur who plans to enter into Turkish market can collect data and information about Turkish market and consumer behaviors from web. In parallel with this example, after a literature review, Ongori and Migiro (2010) assert that uses of ICT ease to get into international markets of small and medium sized organizations. ICTs are used by not only business organizations but also social organizations. For example, many aiding organizations in Africa obtain benefits from ICTs (Molony, 2007). Therefore, ICTs may be beneficial tools for social entrepreneurship as well.

Finally, ICT may be output of an entrepreneurial process as well. Some organizations may choose to produce either tangible (components,

computers and networks) or intangible (software, web pages) ICTs as an output (Heeks, 1999). WhatsApp that were bought by Facebook in 2014 is a good example of ICT as an output of entrepreneurial processes.

FUTURE RESEARCH DIRECTIONS

Continuous technological developments in internet economy cause emergence of new concepts in the field of entrepreneurship such as “e-entrepreneurship” and “netpreneurship”. Today, everything slips back to virtual environment. Wars, loves and so many things are experienced by people in virtual environments now. Therefore, emergence of concepts such as netpreneurship in the field of entrepreneurship is natural. Netpreneurs, they are sometimes called as “Ontrepreneurs”, are entrepreneurs who have ability to run a business largely on internet (Balachandran & Sakthivelan, 2013). At this point, it can be investigated that whether candidates of netpreneurship need different psychological traits and educational backgrounds from candidates of traditional entrepreneurship or not. In addition, generation of people seems to be another important factor that may determine netpreneurship tendency of people. Therefore, it can be researched that whether there are significant differences between members of generation X and Y in terms of tendency of being netpreneur.

In addition to the relationships of entrepreneurship and ICT, the field of entrepreneurship contains some other points of development as well. When the “Management and Organization Studies (MOS)” literature is examined, it can be observed easily that although a limited sensitivity on context has emerged recently (for example in subfield of organizational behavior (Johns, 2006; Morgeson *et al.*, 2010)), the literature is largely context free. A similar evaluation is valid for the literature of strategic entrepreneurship as well. Strategic entrepreneurship is a popular subfield that combines competitive advantage seeking behavior of strategic management and opportunity

seeking behavior of entrepreneurship to reach desirable financial performance (Ireland *et al.*, 2003). On the other hand, scholars of the field seem to overwhelmingly focus on activities of strategic entrepreneurship in developed countries. However, the findings of some previous studies showed us that behaviors of strategic entrepreneurship in emerging economies have unique characteristics (Bruton *et al.*, 2013). Therefore, an increase in number of strategic entrepreneurship studies that are conducted in emerging countries⁴ will be beneficial to understand this context and its effects on strategic entrepreneurship better.

Another recent trend in the field of entrepreneurship seems to make a strong emphasis on emotions (e.g. Cardon *et al.*, 2012; Podoynitsyna *et al.*, 2012; Wolfe & Shepherd, 2015). The studies of entrepreneurship that focus on cognitive side of decision making processes largely has overlooked impact of affect until recently. However, some scholars recently assert that entrepreneurship isn't only a cognitive act (Klein *et al.*, 2013) and affects and cognition often shape processes of decision making jointly.⁵ In parallel with this idea, Hayton *et al.* (2012) proposes that affects foster working memory that stores information that is used as an infrastructure during entrepreneurial decisions. Therefore, studies that discuss and investigate the roles of positive and negative affective situations on various steps of entrepreneurial process will be interesting. In addition, face to face relationships of entrepreneurs often ease to reflect emotions. At this point, consequences of virtual work environment on moods of entrepreneurs may be investigated.

In social sciences, it is often mentioned that a linguistic turn (Alvesson & Kärreman, 2000) is experienced. With this turn, language seems to regain its importance that it lost in periods of Enlightenment and Romanticism (Bonet & Saquet, 2010). According to the view, language isn't solely a basic tool to exchange ideas. It is also an instrument to build the reality. One of the sub branches of this view is studies that focus on rhetoric. Rhetoric is "the ability of 'seeing' the available means of persuasion" in terms of Aristotle (1991:

13). Entrepreneurs need to persuade themselves first and then, some other different actors such as families, inner circles and investors (such as angel investors and venture capitals). Even though various studies (e.g. Brooks *et al.*, 2014; Chen *et al.*, 2009) have recently emerged in the literature that endeavor to link entrepreneurship with rhetoric, number of these studies is still so limited. In addition to these, another research question may be in this point that how and when will ICTs affect rhetorical capacities of entrepreneurs?.

Further, neurosciences are just beginning to create impact on the social sciences (Martin de Holan, 2014). In addition, there is a strong interest (both sides from critical and proponent)⁶ towards neurosciences in MOS field. Many studies (e.g. Lindebaum, 2016; McDonald & Tang, 2014) that have been published in prestigious MOS journals seem to support this claim to a large extent. Some of these studies take a stand on proponents' side; others express their doubts about neuroscience based MOS studies. For example, Lindebaum and Zundel (2013) profess that some MOS researchers who try to link MOS and neurosciences often adopt a very reductionist stance and endeavor to explain some very complex phenomena (such as leadership, management development) with quite simple mechanisms. In a similar vein, entrepreneurship researchers appear to begin fostering sympathy to the mind and its workings. However, entrepreneurship researchers have largely focused on attributes and behavior of entrepreneurs until very recently instead of what and how entrepreneurs think and which factors direct entrepreneurs to think in that ways (Martin de Holan, 2014). Therefore, neuroscientific studies on entrepreneurship that will take some limitations of using views of neurosciences in social sciences into account will be interesting.

Finally, MOS has focused on couple who are working together in a common workplace. Recently, some part of the literature of entrepreneurship has begun to show interest to copreneurs. According to Greenhaus and Callanan (2006), copreneurs are couples who focus on the same entrepreneurial activities. At this point, some

studies that explore antecedents and (positive and negative) consequences of copreneurship may be attractive.

CONCLUSION

In this study, the relationships between two popular concepts, “entrepreneurship” and “information and communication technologies”, were discussed. According to the study, ICTs can be input, output or as a part of entrepreneurial processes. On the other hand, when ICTs are used in a negative way, they can be harmful for entrepreneurial success as well. Therefore, appropriate uses of ICTs must be guaranteed.

KEY TERMS AND DEFINITIONS

Copreneurs: Couples who focus on the same entrepreneurial activities (Greenhaus & Callanan, 2006).

Entrepreneurship (In a Classical Manner): Associated with bringing factors of production together and taking the risk that is stemmed from this activity (Stevenson & Jarillo, 1990).

Information and Communication Technologies (ICT): “Electronic means of capturing, processing, storing, and communicating information” (Heeks, 1999: 3).

Netpreneurs: People who have an ability to operate a business on internet to a great extent (Balachandran & Sakthivelan, 2013).

Nomophobia: A fear of being unable to communicate through a mobile phone or the internet” (Yıldırım, 2014: 8 cited from King *et al.*, 2014: 28).

Ontpreneurs: Entrepreneurs who are working online. This concept is often accepted as synonym with netpreneur by many scholars in the field of entrepreneurship.

Schumpeterian Entrepreneurship: Making new combinations.

ENDNOTES

¹ At this point, there are also some studies (e.g. Rauch & Frese, 2006) in the literature that have some doubts about whether the field of entrepreneurship is a mature discipline or not.

² This stream seems to attribute a positive meaning to personality to a large extent. However, there are some studies (e.g. Klotz & Neubaum, 2016) that attract our attentions to the darker sides of personality (such as

Machiavellianism, psychopathy, narcissism etc.) and their relationship with entrepreneurial consequences. In addition, some scholars (e.g. Miller, 2015) discuss that some personality traits (such as being energetic and high self confidence) that seems to be positive for entrepreneurship at the first point may transform into negative ones (such as aggressiveness and narcissism) later.

³ In effect, there also seems to be a reversed relationship between these variables as well. For instance, Kerr and Nanda (2011) discuss that a desire for personal wealth may trigger the choice of being an entrepreneur.

⁴ According to the Spanish Bank BBVA, emerging countries isn't a monolithic group.

BBVA tends to divide emerging countries into subgroups such as "EAGLEs" and "NEST" (Wassener, 2010). Therefore, research in emerging countries may be conducted in terms of these subgroups.

⁵ In addition, entrepreneurs often experience a mixed of emotions during their decision making processes instead of experiencing only one emotion (Podoyntsyna *et al.*, 2012).

⁶ In effect, there is one another position in MOS field about neurosciences. Critical realist position (e.g. Healey & Hodgkinson, 2014) seems to adopt an intermediate stance in this heated discussion.

Entrepreneurship as the Vantage Point

INTRODUCTION

Entrepreneurship is the dynamic process of creating incremental wealth. This wealth is created by individuals who assume the major risks in terms of equity, time, and/or career commitment of providing value for some product or service. The product or service itself may or may not be new or exceptional but value must somehow be infused by an entrepreneur (Shapero, 1975). Entrepreneurship is an elusive concept and has been defined differently by different authors. Some of them view it as 'risk-bearing'; others call it as 'innovations', and yet others consider it as 'thrill seeking'. Today, an entrepreneur is an innovator or developer who recognizes and seizes opportunities; converts those opportunities into workable/marketable ideas; adds value through time, effort, money, or skills; assumes the risks of the competitive marketplace to implement these ideas; and realizes the rewards from these efforts.

An entrepreneur is the aggressive catalyst for change in the world of business. He or she is an independent thinker who dares to be different in a

background of common events. The characteristics are; personal initiative, the ability to consolidate resources, management skills, a desire for autonomy, and risk taking. Other characteristics include aggressiveness, competitiveness, goal-oriented behaviour, confidence, opportunistic behaviour, intuitiveness, reality-based actions, the ability to learn from mistakes, and the ability to employ human relations skills. Entrepreneurship is an essential element for economic progress as it manifests technology in different ways: a) by identifying, assessing and exploiting business opportunities; b) by creating new firms and/or renewing existing ones by making them more dynamic; and c) by driving the economy forward - through innovation, competence, job creation - and by generally improving the wellbeing of society.

The accessibility of Information technology is a necessity for any entrepreneurial activity. Today technology has its impact on individuals and communities as entrepreneurship does, and hence IT cannot be neglected. In the past two decades, advanced industrial countries with new technology have become driving force of entrepreneur-

Figure 1. Concept of entrepreneurship

DOI: 10.4018/978-1-5225-2255-3.ch263

ship creating economic development (Tavakoli, 2013). Given that entrepreneurship and impact of technology on it have evolved into a distinctive force, which is in line with changes in business optimization.

BACKGROUND

The entrepreneurial revolution has taken hold across the globe and has undeniably impacted the world of business. The younger generation of the 21st century is becoming the most entrepreneurial generation since the Industrial Revolution. There are various personal characteristics, cognitions, and social conditions that affect an individual's choice to pursue entrepreneurial activities. Greenberger & Sexton (1988) discussed five reasons why an entrepreneur wants to start a business. First, they would like to take a chance in the market. Second, they believe their managerial skills are more efficient than those of other people. Third, they believe that their specialty could be developed into an enterprise. Fourth, they have already developed a product or service and they believe that can find a niche in the market. Fifth, this is the only way to start an enterprise and their other options are limited. Ghosh & Kwan (1996) found that there were several reasons that these entrepreneurs started enterprises namely, the individual wants personal growth; they like the challenge; there is more freedom in being a business owner; chance to use one's own knowledge and experience; do not like working for others; they are affected by family or friends; and family tradition. Carter, Gartner, Shaver & Gatewood (2003) explored and compared the reasons that nascent entrepreneurs and non-entrepreneurs to start enterprises and make career choices. The results of indicated self-realization, financial success, roles, innovation, recognition and independence are the main reasons to start enterprises. Wang & Wong (2004) found gender, family experience with business and educational level are significant factors in entrepreneurial interests. Although the concept of

entrepreneurial competencies is used widely by government agencies and others in their drive for economic development and business success, the core concept of entrepreneurial competencies, its measurement and its relationship to entrepreneurial performance and business success is in need of further rigorous research and development in practice (Mitchelmore & Rowley, 2010).

The entrepreneurship approaches are important aspect or components of entrepreneurship development as well as entrepreneurial environment which should be considered, they contribute significantly to the entrepreneurial development success and as well as that of the success of the entrepreneurs. These approaches once again include; ethnicity, location, women, religious, socio-cultural, and youths (Lucky, 2011). Therefore, if these entrepreneurial approaches are being given urgent consideration, they are capable of changing the entrepreneurial scenario of any country and thereby serving as a driver and motivating force in achieving entrepreneurial success. Naudé *et al* (2009) empirically identified the determinants of start-up rates across different sub-national regions and in particular to investigate the role of access to finance on a regional (sub-national) level on start-ups. They find that the most important determinants of start-up rates are profit rates, educational levels, agglomeration as measured by the economic size of a district, and access to formal bank finance. It is also identified that the existence of 'congesting' factors such as increased competition, tougher barriers to entry, monopolistic behavior, and a greater difficulty to be innovative and novel are also influencing. During the last two decades, the development of new technologies and emergence of new business models has enabled the shift from large corporations to small and new ventures (Acs & Audretsch, 1988). Most entrepreneurs simply got tired of working for others, had a great idea they wanted to commercialize, or woke up one day with an urgent desire to build wealth before they retired. So they took the big leap." The country's economic policy environment must be favourable for organizations

to achieve efficiencies in today's global market (Santhi, 2011). It should enable the entrepreneurs to provide a magical touch to an organization, whether in public or private or joint sector, in achieving speed, flexibility, innovativeness, and a strong sense of self-determination. They bring a new vision to the forefront of economic growth of a country.

CHALLENGES FACED BY AN ENTREPRENEUR

In this modern era nothing can be earned easily and the same goes with success as an entrepreneur. Entrepreneurship life is not as easy as it seems the way one sees them in magazines showing them enjoying all facets of life happily. Success waits for those who are ready to face the hurdles and overcome them someday as life goes on (Pride, 2014). The following will make one understand the challenges that an entrepreneur always has to be prepared to face and overcome (Morris, 2014).

1. **Selection the Right Business:** Most of the businesses fail for the reason that they are not real businesses. To do great business (product or service) one should have a great idea. If the business finds a right customer, but the idea chosen to reproduce is illogical everything falls apart. So, every entrepreneur's first challenge lies picking up the right start to go ahead and survive in the market.
2. **Financing the Business:** Financing has always been a key area to be considered for an entrepreneur starts an enterprise. It is the lifeblood of every business organisation, so an entrepreneur should be smart enough to gather funds from different sources, in prior and every entrepreneur should have proper view of where his investments will flow from, which will not hamper the continuity of business.
3. **Finding the Customers:** Finding the right customer is the one most decisive challenge that crops up during the establishment of an enterprise. Enterprises have to be on their toes, as customer is considered the god, and without customers a business is a dead rubber which hurts an enterprise, and right product and service is the solution for finding the right customer. Once an enterprise has the right product or service, customers will grow automatically.
4. **When to Quit a Day Job:** When one plans to start a business, the ultimate question to be answered is to know the right time to quit job. An entrepreneur starts a business just because he wants to, one need to wait for the right time and then take a step ahead. The right time generally is when an individual have a full proof business opportunity or have enough money in the bank that can work on business.
5. **Dealing With Stress for Irregular Incomes:** There is no other way to face off; it's extremely stressful when certainty of business payment is not regular. Living life like that can be extremely stressful, so an entrepreneur need to have the mental fortitude to power on, keep working, and never give up.
6. **Dealing With Competition:** The biggest challenge that comes before every entrepreneur is to deal with stiff competition at every step. Entrepreneurs will find businesses with similar product and trying to keep up with the challenge from the competitor become need of the hour to reap benefits and the best way to flush through this challenge is by maintaining a standard and by grading products which would benefit customers better than competitor's.
7. **Hiring Employees:** Though an enterprise owns the finest technology, encompass the best layout and of course invest a lot of capital, nothing works out unless the business have required manpower to operate them

or to define minutely the force behind the organisational success.

8. **Cash and Time Management:** Management of cash flow is essential for the survival of a business enterprise. At times, many entrepreneurs struggle to pay the creditors, employees, loans, etc. In the same manner, time management might also be the biggest problem faced by the entrepreneurs. If the entrepreneur manages both time and cash simultaneously, the targets could be accomplished.
9. **Marketing Strategy:** Strategy to go with is a question which arises in different phases of a business and this is the next big hurdle which has to be planned in advance as the right strategy sets you up for success. Speaking of a perfect marketing strategy, it can be devised by having a clear awareness about the stage of a product or service in its lifecycle.
10. **Business Expansion:** When an entrepreneur starts an enterprise and is running successfully accomplishing the objectives, after a while a question squeezes him i.e. what further can be achieved and of course why not as a dream never stops at one stage. Entrepreneurs can solve this problem by creating new processes that focus on task delegation. Many entrepreneurs do this at one point or the other that is to delegate the task to subordinates when it needs to be.

MEASURES OF ENTREPRENEURIAL ORIENTATION

A vast majority of scholars agree with the view that the degree of Corporate Entrepreneurship can be measured by three dimensions: innovativeness, proactiveness and risk-taking, as mentioned by (Covin & Slevin, 1991; Miller & Friesen, 1983). However some authors, such as Lumpkin and Dess (1996) argue that five dimensions, should be used to measure entrepreneurship; namely autonomy,

competitive aggressiveness, proactiveness, innovativeness and risk-taking. Kreiser, Marino, and Weaver (2002) suggested including growth orientation as the fifth, independent measurement of entrepreneurial management. Based on the proposition of different authors, the descriptions of each of these dimensions are discussed in detail.

Autonomy

Autonomy refers to the independent action of an individual or a team in bringing forth an idea or a vision. In general, it means the ability and will to pursue opportunities, even though factors such as resource availability, actions by competitive rivals, or internal organizational considerations may change the course of the initiative, but not sufficient to extinguish it (Lumpkin & Dess, 1996). Modern firms are increasingly encouraging entrepreneurship at all levels of the organization. To foster entrepreneurial attitudes and behaviour, managers must give significant discretion to employees. Nyström (1979) described it is principally a decentralized, curious and open-minded organization culture that enables firms to meet the challenge of discovering and forming new possibilities and application areas. Corporations do not carry out their innovation activities in isolation of their research labs, but building and tightening the co-operation with their consumers or even competitors have become ever important (Christensen & Raynor, 2003).

Innovativeness

Based on Schumpeter's concept of entrepreneurship, innovativeness refers to the creation of new products, services, processes, technologies and business models. Economically, innovation is the combination of resources in a new and original way. Entrepreneurially, it is the discovery of a new and better way of doing things. Kreiser, Marino, & Weaver (2002) expanded the definition that by regarding innovativeness as the capability, capacity and willingness of an enterprise to

support creativity and experimentation to solve recurring customer problems. Innovation is not simply about generating creative ideas, but also involves the commercialization, implementation and the modification of existing products, services and new ways to meet market demand via new resource combinations. Accordingly, innovation lays at the heart of the entrepreneurial process and is a means of opportunity exploitation. Innovation is not a characteristic of the individual entrepreneurs, but of their actions (Gartner, 1988).

Proactiveness

Proactiveness reflects an action-orientation with a forward-looking perspective reflected in actions taken in anticipation of future demand (Covin & Slevin, 1989; Lumpkin & Dess, 2001). Kreiser, Marino, & Weaver (2002) define proactiveness as the aggressive execution and follow-up actions to drive an enterprise toward the achievement of its objectives by whatever reasonable means required. Proactive firms constantly seek new opportunities by anticipating future demand and developing products and services in regards of unmet customer needs. They tend to be industry leaders in regards of developing new products, procedures, or technologies (Lumpkin and Dess, 1996). Consequently, they are also likely to be initiators in the creation or discovery of new attributes that lead to an increase in value creation (Foss et al, 2007). As such, proactiveness has certain underlying attributes like the anticipation and quick reaction to opportunities; the attitude to being a pioneer or fast follower; and the high regard for employee initiatives (Stevenson & Jarillo, 1990).

Risk-Management

Before elaborating risk-management, the term propensity to take risk needs to be defined. Risk-taking refers to the willingness to commit significant resources to opportunities that involve a reasonable chance of costly failure. Brockhaus

(1980) has found that some entrepreneurs may be cautious and risk averse under some circumstances and risk-taking in others. While risk bearing is an important element of entrepreneurial behaviour, entrepreneurial managers found to be „carefully brave” that is they tend to take risk grudgingly and only after they have made valiant attempts to spread their risks on capital sources and resource providers (Stevenson, 2006). Although all venturing attempts face uncertainty and the possibility of painful mistakes such problems take a more acute form for entrepreneurial managers, vis-à-vis small business founders (Aldrich & Martinez, 2001). Hence, the measurement of the extent to which individuals differ in their willingness to take risk is fraught with difficulty, especially when it is based on subjective evaluation.

Growth Orientation

A considerable body of literature has demonstrated that growth orientation in itself represents an entrepreneurial characteristic (Cooper, Woo, & Dunkelberg, 1989). Vesper (1980) pointed out that many business owners never intend their business to grow over what they consider to be a controllable size. Hence, it is necessary to go beyond the notion of corporate life cycles and stages to conceive of an entrepreneurial firm (Carland, Hoy, & Carland, 1984). Glueck (1980) distinguished between entrepreneurial ventures and what he termed family businesses by focusing on the needs and preferences opposed to those of the business. The critical factor in distinguish entrepreneurial managers from non-entrepreneurial ones, and in particular small business owners, is the presence of a sound and articulated growth objective.

IMPACT OF ENTREPRENEURSHIP IN ECONOMIC DEVELOPMENT

Economic development essentially means a process of upward change whereby the real per capita income of a country increases for a long

period of time. The crucial role played by the entrepreneurs in the western countries has made the people of underdeveloped countries conscious of the significance of entrepreneurship in economic development. India after independence had a challenge of recovering back from having a sluggish economic development. There were many platforms to develop the economy of which few were like direct participation of the government, Regulation of private sector economic, increased exports business and lastly the Act of Entrepreneurship, such as Start-Ups, Joint Ventures.

Entrepreneurship is the act of thinking creatively and en-cashing their opportunity being selfish personally and indirectly helping in Economic development thus possessing more impetus, and the focus has been on entrepreneurial activity in which the individual's involvement has a direct ownership interest in the business. Countries where more entrepreneurship is motivated by an economic opportunity recognized than by necessity have higher levels of income (Lal & Clement, 2005). We are finding "How entrepreneurship is good for economic development?" for this we need to find meaning of entrepreneurship and self employment. Entrepreneurship may not lead to economic development as there is no mechanism to link the activity to development. We have learned from the studies and trend that self-employment declines as economies become more developed. So we can conclude that when economies remove people from self-employment, there can be an increase in development. The important role that an entrepreneurship plays in the economic development of an economy can be put in a more systematic manner as follows:

1. Promotes capital formation by mobilizing the idle saving of the public.
2. Reduces the concentration of economic power.
3. Stimulates the equitable redistribution of wealth.
4. It also induces backward and forward linkages which stimulated the process of economic development in the country.
5. It promotes country's export trade.

INFORMATION TECHNOLOGY IN ENTREPRENEURSHIP

The advent of information technology has changed all the aspects of the world in the third millennium to a great extent and the entrepreneurship in particular. IT contributes to the entrepreneurship in different ways. It is now a widely held view that the world economy has entered a much more complex phase where individual national economies have become inextricably linked. In this new world economy, resources and markets have ceased to have the indelible national identity of the past. With the changes in businesses today, information technology (IT) plays a vital role in business survival.

Deans and Kane (1992) found that information technology (IT) plays an indispensable role in making a company successful under uncertain and turbulent economic conditions. Pearce et al. (2007) introduces information technology in line with social entrepreneurship as leverage for the sustainable development. Entrepreneurial individuals combine many personality traits - innovativeness, risk taking, pro-activeness in the sense of doing what is necessary to realize their ideas combined with shouldering responsibility for success or failure (Covin and Slavin, 1989). Entrepreneurship is defined as the process of creating value by combining a unique mix of the aforementioned concepts in order to take advantage of an opportunity (Morris and Sexton, 1996).

IT TOOLS IN ENTREPRENEURSHIP

In order to strengthen the society of learning and knowledge, Despite a certain setback, with the application of the IT strategy, will support the development strategy of all entities and by

learning from the world's most prominent business practices, it is possible to overcome the development gap and define new development potentials of in the area of entrepreneurship. As specified by (Duncombe, 1999) the tools of IT for Entrepreneurship development are:

1. **E-Mail:** E-mail enables fast and relatively cheap communication internally, between networked computers, and externally, within the locality, regionally and world-wide. An e-mail message, and any accompanying computer files, can be sent via the phone line within a few minutes to any global destination.
2. **Internet and World-Wide Web:** Connection to the internet enables communication with a global network of computers, and access to enormous quantities of information, providing for multi-media content based on text, pictures, sound, graphics and moving images.
3. **Local Networking:** Enterprises gets benefited from creating internal networks by connecting computers together by means of cabling. This enables them to communicate with each other, to share data files, printers, faxes, etc. Computers can be linked within a single location known as a Local Area Network (LAN) or between multiple locations, known as a Wide Area Network (WAN). Internal networks can also be connected to external networks such as the World Wide Web (Internet).
4. **Cloud Computing Tools:** cloud computing tools like Cloud ERP, Marketing automation, inbound marketing, lead tracking, sale cycle management have strengthened the enterprises to go and conduct their business in much larger scale.
5. **Mobile Communications:** Mobile communications based on new digital technology, allows the entrepreneurs to answer queries from the customers immediately, and to reach the staff working away from the of-

fice, no matter in which location they are. In developed countries mobile phones are now part of the business fabric and have been extremely rapid.

6. **Electronic Commerce:** E-commerce will have a significant effect on the Entrepreneurship. E-commerce has already been in use, through the telephones and credit cards, electronic payment and money transfer systems and smart cards. However, it is through the medium of the internet and online services that rapid expansion is likely to take replace the traditional way of doing things.

The Latest emerging tools of Information Technologies for Entrepreneurship that will be making headlines in shaping and development of Entrepreneurship ventures are:

1. **Social Technologies:** Enterprises will also be benefited by improved social networking sites like Facebook, Twitter, etc where information always flows and will be garnered by the one in need of the information.
2. **Cognitive Networks, Big Data:** Communication systems handle volumes of data generated by embedded devices, mobile users, enterprises, contextual information, network protocols, location information and such.
3. **Green Communications:** Green Communications created the Participatory Internet to answer connectivity challenges of network densification, mobility and sustainability.
4. **Smarter Smartphones, Connected Sensors:** The indisputable rock-start of devices is the smartphone, and its future can't be brighter, these ubiquitous communication devices continue evolving, and so are prices which, driven by cost and performance improvements in digital technologies, are falling rapidly.

5. **Network Neutrality, Internet Governance:** The Internet has been operating since its inception under “open” principles, i.e. an open standards-based network that treats all traffic in roughly the same way, i.e. no connection blocking, bandwidth transparency, universal connectivity, and best effort service.
6. **Molecular Communications:** Molecular communication is an emerging paradigm where bio-nanomachines communicate to perform coordinated actions. Molecular communications utilize biological molecules both as carriers and as information.

FUTURE RESEARCH DIRECTIONS

People live in a day and age in which empowerment and individuality are embraced and this approach is gaining momentum. The future without a doubt belongs to entrepreneurs and this is something to be really excited about. The future is headed in a direction we have never seen before and changes are vastly innovative and fast approaching. Consumers are definitely privy to this fact and more and more they are taking their business to a thriving entrepreneur over a corporate entity. If the basic idea of being own boss isn't appealing enough all of the other perks that come along with building a brand that belongs all to his own blood, sweat, tears should seriously make him reconsider his career path. A few of the momentous shift happening in the way of entrepreneurship are namely; Digital wanderers, Personal brands, Bonding together, Heart-Centric businesses, and No more cost controls. This study articulates the potential importance of entrepreneurship and to put forth the various dimensions it paves. But the research on how to establish control and appeal is limited in this study. For further studies, it is important to explore how the entrepreneurs can establish the formal appeal and control system, and keep transparency in establishing the businesses.

CONCLUSION

Entrepreneurship is the lifeblood of any economy. Indian entrepreneurs are more about overcoming barriers, obstacles, inspiring and surmount in their relevant fields. Entrepreneurship is one of the important segments of economic growth and development. Innovation is a key factor that an entrepreneur brings in an overall change through which it is possible for the maximum social good. As it is said that, 'Failures are the stepping stones for success.' An entrepreneur life is not a bed of roses, as they face many obstacles in the way of entrepreneurial achievement.

Information technology has created dramatic developments in various spheres of entrepreneurship and is regarded as most important tool of modern entrepreneurship. Entrepreneurship is requisite of technological development is infrastructure of entrepreneurship. Furthermore, entrepreneurship can tell the condition of a nation, it acts as a central cohesive source of support and stability, not only to the society but also to the whole economy given the impetus of technological tools and their application. Last but not least one can say that, where technological entrepreneurship exists, dwells development, similarly progress and prosperity.

KEY TERMS AND DEFINITIONS

Business: A body involved in buying and selling of goods & services to the end-user.

Cash Flow: The difference between the company's cash receipts and its cash payments in a given period. It refers to the amount of money actually available to make purchases and pay current bills and obligations.

Economic Development: Economic Development is an act of creating wealth and wellbeing among society.

Entrepreneur: An Entrepreneur is the impetus which drives the nation to an elevated stage where one has the ability to seize every opportunity put forth to realise dreams.

Entrepreneurship: Entrepreneurship is the process of launching an enterprise in order to generate income as well as enrich economic development.

Information Technology: A creation which makes things easy cum advanced.

Innovation: Innovation is process of creating something new and creative which is a value addition.

Entrepreneurship Concept, Theories, and New Approaches

José Manuel Saiz-Alvarez

Tecnologico de Monterrey, Mexico

Martín García-Vaquero

Nebrija University, Spain

INTRODUCTION

In today's world, have a good number of active entrepreneurs is key to determining good corporate health of a country. Entrepreneurs discover and exploit new business opportunities guided by intuition (Saiz-Alvarez, Coduras, & Cuervo-Arango, 2013) and risk control, while motivating social change. Complementary to entrepreneurs, capitalists only invest their money searching for share profitability, and managers, as decision-makers, foster mainly first-order competitive advantages in the company (R&D and innovation) by enhancing competition (Cuervo, Ribeiro, & Roig, 2007). When competition is strong, firms are achieving continuous improvements over time, which benefits their stakeholders.

Contrary to Van Praag and Van Ophem (1995), who affirm entrepreneurship was first studied in Cantillon's *Essai sur la nature du commerce en général*, published in 1755, the concept of entrepreneur (in the sense of merchant) was first studied in Spain in the second book of Tomás de Mercado's *Tratos y contratos de mercaderes y tratantes discidos y determinados* [Deals and Contracts Applied to Certain Merchants and Traders], published in 1569, and reedited with a few tweaks in 1571, as *Suma de tratos y contratos* [Treaty on Deals and Contracts]. Regarding entrepreneurship, Tomás de Mercado approves new business and exchange trade, only if they are consistent with the moral rules based on not taking advantage of others by using abusive prices and

interest rates, or by conducting unfair agreements, both socially and economically.

This connection between moral acts and entrepreneurship continues, with exceptions, until today. In fact, entrepreneurs must be involved in the study of sources for discovering, and achieving new business opportunities, in order to exploit them (Shane and Venkataraman, 2000). As a result, and given the impact of entrepreneurship in a country, «contemporary economic theory recognizes entrepreneurship as an independent factor of production on a more-or-less equal footing with land, labor, and capital» (Hébert and Link, 1989, p. 40). The objective of this work is to define entrepreneurship, and the classical and new theories of entrepreneurship, both from economic and psychological perspectives.

BACKGROUND

ENTREPRENEURSHIP: CONCEPT

Entrepreneurship can be analyzed following a multiple perspective, generating a multidimensional concept (Bula, 2012). While the study of entrepreneurship began for Economics and Managerial Sciences in the second half of the XVI century, the first psychological studies about this issue were published in the 1960s with the seminal works of McClelland (1965), Rotter (1966), and Atkinson (1966). These authors focused their efforts on trying to explain how individual and social motivation is one of the most important psychological factors

to explain entrepreneurship, and also discover that imagination, power distance and willingness for taking risks are key factors for success. Moreover, when the possibility of achievement gets higher, entrepreneurial propensity rate increases (Kalkan & Kaygusuz, 2012).

In order to entrepreneurs to have success, they must identify business opportunities (Stevenson & Jarillo, 1990; Barringer & Ireland, 2006; Timmons, 1999; Mariotti & Glackin, 2010), be able of choosing and managing entrepreneurial careers (Haynie & Shepherd, 2011), and be capable of acting entrepreneurially (McMullen & Shepherd, 2006; Shepherd & Patzelt, 2011) by being adapted to business circumstances given their capacity of resilience to failure.

The mentality of entrepreneurs differs, as they are driven by *entrepreneurial alertness* (Kirzner, 1979) defined as a distinctive set of perceptual and cognitive processing skills directed to opportunity recognition processes. As a result, and given this entrepreneurial alertness, only the most risk-lovers tend to be successful while managing their businesses, as «the entrepreneur always searches for change, responds to it, and exploits it as an opportunity» (Drucker, 1985, p. 25).

Entrepreneurship is the act of innovation involving endowing existing resources with new wealth-producing capacity (Drucker, 1985), as the nature of the decision making context with entrepreneurs' decisions (Alvarez & Barney, 2005). As a result, «the entrepreneur is someone who is specialized in taking responsibility for and making judgmental decisions that affect the location, form, and the use of goods, resources or institutions» (Hébert & Link, 1989, p. 213).

Entrepreneurs are the business core of a company, especially in newly-born firms. Given the above definitions, entrepreneurship can be defined as the type of business strategy focused on the creation of jobs, social wealth, and profit by optimizing the use of productive and commercial resources.

Moreover, Ahmad and Seymour (2008) affirm that entrepreneurship is the phenomenon

associated with entrepreneurial activity, that is, «the enterprising human action in pursuit of the generation of value, through the creation or expansion of economic activity, by identifying and exploiting new products, processes or markets» (p. 9). In this sense, Lumpkin and Dess (1996) affirm that the essential act of entrepreneurship by launching new ventures, either by start-up firms or through internal corporate venturing, and is accomplished by entering into new or established markets with new or existing goods and services. Entrepreneurial activities theoretically guided by some theories of entrepreneurship that will be analyzed in the next section.

THEORIES OF ENTREPRENEURSHIP

The Neoclassical School

The combination of psychological and managerial characteristics in entrepreneurs is fundamental to understand their behavior. In this sense, Hébert and Link (1989), cited by Audretsch (2003), have identified three distinct intellectual traditions in the development of the entrepreneurship contemporary literature: [1] the German Tradition, based on von Thünen (2015[1875]) and Schumpeter (1997[1911]), that has the greatest impact on the contemporary entrepreneurship literature; [2] the Chicago Tradition, rooted on Knight (1921) and Schultz (1980), and [3] the Austrian Tradition, based on von Mises (1949), Kirzner (1979), and Shackle (1968). We can add an emerging intellectual traditions formed by Latin American and Spanish researchers, given the socioeconomic peculiarities of these countries that have been barely studied so far in the economic literature on this issue.

In his classic treatise, *Theorie der wirtschaftlichen Entwicklung. Eine Untersuchung über Unternehmengewinn, Kapital, Kredit, Zins und den Konjunkturzyklus* [Theory of Economic Development. A Study of Entrepreneurial Profit, Capital, Credit, Interest Rate, and the Business

Cycle], Schumpeter (1997[1911]) proposes a theory of creative destruction, where new firms equipped with the entrepreneurial spirit displace less innovative incumbents, leading to economic growth, as a «function of entrepreneurs is to reform or revolutionize the pattern of production by exploiting an invention, or more generally, an untried technological possibility for producing a new commodity or producing an old one in a new way» (Schumpeter, 1977[1942], p. 13). As a result, Schumpeter (1934) defines entrepreneurs by focusing on adopting innovation and new business strategies that can take several forms: [1] the introduction of new methods of production to increase productivity, efficiency, and EBITDA (Earnings before Interests, Taxes, Depreciation, and Amortization); [2] the introduction of new goods or quality thereof; [3] the opening of new markets; [4] the conquest of new sources of supply of new materials or semi-elaborated goods; and [5] the entry to new market niches or sectors. In short, entrepreneurs identify opportunities, assemble required resources, implement a practical action plan, and harvest the reward in a timely, flexible way (Sahlman & Stevenson, 1991).

Regarding the Chicago and Austrian Traditions, entrepreneurs attempt to predict and act upon change within dynamic and uncertain markets (Knight, 1921). According to this School of Thought, free market conditions determine competition on global markets, so public intervention is negative, as it detracts economic resources to private firms. As a result, entrepreneurs are immune from control of rational bureaucratic knowledge (Weber, 1947), so they can be defined as the professionals who discover new business opportunities, after having taken into account commercial and financial risks, and the subsequent creation of new economic activity, often through the creation of new business organizations (Reynolds, 2005).

For this School, entrepreneurs must compete in a globalized business world, by thinking globally and acting locally (“glocalization”). Therefore, entrepreneurs must keep labor costs in line with

productivity, and must achieve a steady increase in production in order to satisfy existing market niches, and enter into new markets. If that steady growth is not achieved, there is a risk of business stagnation, which is detrimental to the company’s stakeholders.

Entrepreneurs, as coordinators and arbitrageurs, as well as the main judgment-based agent of production in the economy (Hébert and Link, 1988, cited by Bula, 2012), are always speculators, as they deal with the uncertain conditions of the future, so it is vital for them to have success in the correctness of their anticipation of uncertain events (Von Mises, 1949).

In a globalized socioeconomic world, entrepreneurs create social and economic wealth by bringing together unique packages of resources to exploit marketplace opportunities (Ireland, Hitt, & Sirmon, 2003) guided by opportunity recognition (Gaglio & Katz, 2001; Shanke & Venkataraman, 2000; Kirzner, 1979), and by creating a previously-unperceived opportunity for profit (Von Mises, 1949). In short, and as Grebel, Pyka, and Hanusch (2001) gather from Schumpeter and the Neo-Schumpeterian School, «no entrepreneur—no innovation — no dynamics — no evolution» (p. 7).

The New Keynesian School

Entrepreneurship is marginal in the new Keynesian school, as labor markets only deal with the development of efficiency wage models. Despite this issue, the implementation of public policies to support private entrepreneurship generates crowding-in effects, although public spending is increased, so new entrepreneurs are created.

By combining macroeconomic government spending data with individual-level entrepreneurship data, Islam (2015) finds a positive relationship between increasing the share of social and public goods at the cost of private subsidies and entrepreneurship, while confirming a negative relationship between total government consumption and entrepreneurial activity.

In our globalized world, informal ventures are increasingly important, and are influenced by economic and political factors affecting entrepreneurship. In this sense, Autio and Fu (2015) study the influence of economic and political institutions on the prevalence rate of formal and informal entrepreneurship across 18 countries in the Asia-Pacific region during the period 2001-2010, and find that the quality of institutions influences on both formal and informal entrepreneurship. Higher quality of economic and political institutions doubles the rates of formal entrepreneurship, and halves the rates of informal entrepreneurship. Moreover, both economic and political institutions have a complementary effect on driving entry into formal entrepreneurship, whereas only direct effects are observed for informal entry.

Entrepreneurs for New Keynesian economies are benefited from public expense and investment. In effect, government's Keynesian functions stimulate demand for goods and services through purchases and income redistribution; while government's Schumpeterian economic policy lowers the cost of innovation through regulatory requirements, R&D subsidies and innovation, and the acquisitions of expensive and new technology. These two economic-based Schools of thought are complemented with psychological-based Schools, as entrepreneurship is formed by a mixture of both economic and psychological thought.

Psychological-Based Schools

Regarding entrepreneurship, five Schools of thought can be distinguished, as follows: [1] *Functionalism*, where theorists try to explain thoughts, the learning process, instincts, and decisions simply describing what entrepreneurs do, without asking how they do it.

In this sense, is of interest to link resilience and functionalism, as rule-governed behavior turns people insensitive to contingencies, so a higher capacity of resilience is achieved; [2] *Behaviorism*, rooted on Functionalism, is focused on both

human and animal behaviors, so it analyzes the reasons why entrepreneurs act; [3] *Gestalt*, where human mind interprets data through several norms, laws, and organizational principles, so partial information can be completed. This completeness is necessary to make decisions with imperfect or asymmetric information, as is normal in the daily operations done by companies; [4] *Humanistic Psychology*, based on human motivation and on satisfaction of needs, has a direct influence on entrepreneurs, as they want to be happy by achieving corporate goals, and [5] *Cognitivism*, as well as Behaviorism, studies the mind through scientific experimentation, but differs from Behaviorism by accepting that psychologists can study and understand the inner workings of mind and mental processes, so psychoanalysis is rejected given its subjectivity.

These psychological theories applied to entrepreneurship complement economic and managerial theories on entrepreneurship, in order to have an overview into the entrepreneurial behavior. Entrepreneurs with better growth prospects have a high need for power and independence (Duchéneau and Orhan, 1998), as the need for achievement and competition is positively correlated with the result of the company. Moreover, entrepreneurs have a greater need for achievement (Box, White, and Barr, 1993).

The influence of psychological aspects on entrepreneurs is also seen in the modern theories of entrepreneurship that will be seen in the next paragraph.

NEW APPROACHES OF ENTREPRENEURSHIP

Jack-of-All-Trades Theory

Theoretically developed by Lazear (2005), and mathematically by Kaiser (2012), entrepreneurs' main task is to organize professional teams ("generalists"/"specialists") by combining intel-

lectual capital, as the sum of human capital, relational capital, and structural capital (Saiz-Alvarez, 2012), physical capital and ideas to innovate, and to create product and services to actual and prospective clients. According to this entrepreneurial theory, only generalists (“jacks-of-all trades”) become entrepreneurs, as they assemble production factors, and have knowledge, skills and working abilities in a large number of areas, especially when entrepreneurs are individuals. As a result, and according to Kaiser (2012): [1] individuals with more balanced skill sets are more likely to become entrepreneurs; [2] the supply of generalists entrepreneurs is smaller for production processes, as they require a large number of independent skills; and [3] generalists entrepreneurs have, on

average, a more balanced human capital strategy than specialists.

O-Ring Theory

Seminally developed by Kremer (1993), and theoretically by Fabel (2004), the O-Ring Theory deals with abilities, and product, task, and service quality in firms, as different abilities and skills are supplied by different individuals with different capacities. Team work is essential in this theory, as if a group member fails to fulfill the task (“specialists”), the entire project can also fail. The more able the team, the more per capita capital is used, so it is preferably to limit the size of the team, as more per capita capital must be used.

Resources— and Capabilities— Based Theory

This theory can be seen as an “inside-out” process of strategy formulation, as the entrepreneur looks at what resources the firm possesses to assess their potential for value generation defined in a business strategy to capture the maximum value in a sustainable way. These financial, physical, human, technological, reputational, and organizational *resources* are inputs to be taken into account for the production process, while *capabilities*, defined as the capacity for a team of resources to perform some task or activity, constitute the main source of the firm’s competitive advantage.

One of the keys to have success when applying this theory into practice is to efficiently apply *routines*, defined as those regular and predictable patterns of activity which are made up of a sequence of coordinated and repeated (*learning-by-doing*) actions done by individuals. As a result, econo-

mies of experience are created, and sustainable and actions guided by appropriability.

Achieving sustainability is fundamental for firm’s reputation and good economic results in the long term. The four main elements for the sustainability derived from resources are: [1] *durability*, defined as the rate at which resources depreciate or become obsolete; [2] *replicability*, when acquisition of resources is done inside the organization. The more complex the organizational routines are, the more difficult it will be to replicate them (Grant, 1991); [3] *transparency*, as imperfect information creates inefficiency-based problems; and [4] *transferability*, when rivals can easily acquire resources and capabilities, so leading positions can be in danger.

Successful firms must hire the best human resources, as well as to renew the level of capability per unit of activity and to constantly invest, if they want to be leaders in their sectors. Complex organizational capabilities pose a huge barrier

for other firms to enter the market, and especially when economies of experience are well developed.

Theory of the Optimal Triangle

Companies having a high level of business growth and motivation, influence positively on the formation of new business ideas. It is therefore essential that emotional characteristics close to the ability to work and enthusiasm must be developed to take forward the company. Without enthusiasm, mainly in start-ups, it is impossible for firms to survive in the global market.

Business success is positively related to the level of training, participation in previous projects, business experience, and the number of founders. These factors, however, can change by other endogenous variables, such as debt, product prices, stakeholders' attitudes and investments, purchases, rotation sales, and wages, and exogenous factors, such as energy prices, external shocks, and country risk, among others.

We propose to summarize these variables in three key terms: entrepreneur, business ideas, and capital, as shown in Figure 2. Successful entrepreneurs are at the base of the triangle, because they support entrepreneurs, as they are fuelled by intellectual (as the sum of human, relational and

structural capital), physical, and financial capital. The combination of entrepreneurial resources and capacities, working experience by learning-by-doing, formation, and capital determine the optimal situation for the company. As seen in Figure 2, this point is between the vertices "entrepreneur" and "capital", as they are fundamental to have business success.

CONCLUSION

Based on Information and Communication Technologies (ICTs), entrepreneurship can be classified as: [1] *Intraentrepreneurship* or *Corporate venturing* (Sharma and Chrisman, 1999), defined by the type of entrepreneurship focused on fast trucking product development to take advantage of new business opportunities or to assess feasibility of new processes or designs; [2] *Traditional entrepreneurship*, that according to Brunet and Alarcón (2004), can be classified as: [a] *Novice entrepreneurs*, when they manage their first firm; [b] *Habitual entrepreneurs*, that are classified as *serial entrepreneurs*, when they sell their original ventures to buy and develop new ones, and [c] *Portfolio entrepreneurs*, when they do not sell their original ventures and buy others, so a cluster

is created; [3] *Solidarity Entrepreneurship* (Saiz-Alvarez, 2015), where firms are guided by human values based on solidarity and not for profit, and [4] *Social Entrepreneurship*, mainly formed by cooperatives, whose aim is to maximize the impact of the company on the population searching for social wealth. In this sense, and after having analyzed data from 106,484 individuals in 26 nations, Stephan, Uhlaner, and Stride (2015) confirm joint effects on social entrepreneurship of formal regulatory (government activism), informal cognitive (post-materialist cultural values), and informal normative institutions, through socially supportive cultural norms, or weak-tie social capital.

KEY TERMS AND DEFINITIONS

E

Capability: Capacity for a team of resources to perform some task or activity, what constitutes the main source of the firm's competitive advantage.

Entrepreneur: Individual who starts a new business or adopt a new strategy in an existing organization.

Entrepreneurship: Business strategy focused on the creation of jobs, social wealth, and profit by optimizing the use of productive and commercial resources.

Glocalization: Term created by the combination of «global» (think global) and «local» (act local).

Intellectual Capital: Combination of human, structural and relational capital.

Resilience: An individual resistance to failure, usually in business.

Resource: Inputs to be taken into account for the production and commercial processes.

Open Data and High-Tech Startups Towards Nascent Entrepreneurship Strategies

INTRODUCTION

Open data can be defined as freely, accessible, online data, which are available and can be reused. They are provided under open access allowance so that the data can be reused without restrictions (Jetzek et al., 2014). They can be used for the development of applications which improve citizens' life. A way to boost the development of innovative applications is by hosting hackathons, workshops and conferences (Zuiderwijk et al., 2015).

A definition for a hackathon determines hackathon as an event where people come together in order to engage in creating and launching a new or finished application, which will solve citizens' problems (Rosell et al., 2014). Hackathons are designed to support the use of open data which will benefit both government and citizens (Sieber & Johnson, 2015). Governments desire to scrimmage both citizens and developers to expand an application using open data which are developed, promoted and distributed through hackathons. According to researchers, there are many motivations to persuade developers to participate in a hackathon (Komssi et al., 2015). By hosting these competitions, governments wish to inform about the concernment and the use of open data while they are also supporting the expansion of new applications. These hackathons are frequently consolidated with prize money for participants (Johnson & Robinson, 2014).

Open data are free and accessible, so is beneficial for researchers, government and society. The benefits of open data could be categorized into political and social. Providing the sharing of scientific data is not only a technological issue. It also includes organizational models and research practices, as well as it contains institutional, legal and economic factors (Sa & Grieco, 2016). Several scientific journals support the reveal of experimental data thus data can be reused, reproduced and confirmed (Hossain et al., 2016). Some examples of these benefits are the increased transparency, the accountability, the participation and self-empowerment of citizens to economic growth and the stimulation of competitiveness and innovation (Viscusi et al., 2014). There are two significant benefits concerning the release of open data. The first regards the increased participation of citizens in government, the transparency and melioration of decision-making and the understanding of smarter government tactics through data. The second benefit is the release of data by startups and new businesses in order to expand innovative applications (Conradie & Choenni, 2014).

Open data contains an ecosystem, which displays the relationship among government and innovators and citizens, which is furthermore involved within the larger environment, such as the economy, legal system, and policy expertise (Zuiderwijk & Janssen, 2014).

Previous researchers only describe the activities which are necessary to host the contest (Grabowski et al., 2015, Lee et al., 2015, Rosell et al., 2014). There is limited previous research not only on what motivates the developers to participate in open data competitions, but also on the benefits and challenges which are caused from the use of open data. Furthermore, researches focus on factors that affect nascent entrepreneurs' decision to create a startup but researchers in the field of open data and hackathons relative researches are limited.

The objective of this chapter is to present a framework in order to examine the impact of motivations, benefits and barriers of the use of open data in the participation in hackathons and to develop a startup based on their applications.

The structure of this chapter is as following: After the introductory section, a theoretical background is provided about open data and hackathons. Results of previous surveys support this background. The chapter ends up with conclusions, suggestions for future research and limitations.

BACKGROUND

Open Data

According to Worthy, (2014), open data are defined as the reuse of information and the publishing of government data in a reclaimable form. Data which have been published in an open data format would be available to the public to be reused without limitations (Attard et al., 2015). So developers in hackathons will have the opportunity to use them in order to develop their applications for citizens.

Open data contains an ecosystem, which displays the relationship among government, innovators and citizens. Also, it is involved within the larger environment, such as the economy, legal system, and policy expertise. The open government ecosystem contains relationships between government and innovators from technology sectors, private industry, and academic institutions. Their aim is to transform the form of new data

standards, to investigate new designs of information systems and new technology platforms that permit the expansion of information or technology resources for the future.

The major actors, who contribute in open data are data providers, open data legislators, open data facilitators and many different kinds of open data users, such as citizens, researchers, journalists, developers, entrepreneurs and academics. These actors have various interests and these interests may vary (Viscusi et al., 2014).

The first actor named "Data Providers", consists of the organizations that provide free data. They are commonly public administrations that have many data but they do not have the abilities or resources to use them in the form of data or expand services with them. These organizations provide data to improve the national economy, allowing businesses and citizens to take advantage of them. The second actor is "Service Providers". They offer services related to data and can improve the revenue by the treatment services. The third actor is "Application Developers". They cooperate with partners developing applications related to open data or use open data as completed with their own data in their applications. They develop applications and service using data dispensing by the previous actors. The next actor is "Application Users". They consume data. This process can be done with the development of applications and services. A user can be a customer, a citizen or a business. A customer is defined as a user who has acquired a commercial application from an application store. A citizen can be defined as a user who uses the application personally as a citizen. A business can be defined as a user who uses the applications in his own business. The final actor is "Infrastructure and Tool Providers". They provide the necessary tools supporting the expansion of applications based on open data. These tools are tools providers, cloud service providers, market place providers (Immonen et al., 2014).

The purpose of a good government is to interact with users or citizens, business, and civil sector organizations. Other relationships are referred among public managers and citizens, civil society

organizations and businesses that allow government to detect what types of government data and information is needed and what data or government information services estimate as transparency.

There are two significant benefits concerning the release of open data. The first regards the increased participation of citizens in government, the transparency and melioration of decision-making and the understanding of smarter government tactics through data. The second benefit is the release of data by startups and new businesses in order to expand innovative applications (Conradie & Choenni, 2014). An essential way for actors to be informed about the use of open data is by hosting hackathons (Zuiderwijk et al., 2015).

The benefits of open data could be categorized to political and social. Some examples of these benefits are the increased transparency, accountability, participation and self-empowerment of citizens to economic growth and stimulation of competitiveness and innovation, to name a few (Viscusi et al., 2014). Another benefit is the accessibility of information to wider approach and the allowance to induce innovative usage and application (Roy, 2014). Additionally, Sieber & Johnson, (2015) categorize benefits as political and social, economic, operational and technical, which increase transparency, accountability and civil participation. Open data supports accountability, enhance trust and boost citizen satisfaction. Citizens can generate better ideas, think about alternatives and make better decisions.

As far as businesses, open data can increase several benefits for them. These benefits contain economic growth, innovation, empowerment, participation and new services. Despite the opportunities which are derived for businesses using open data, many businesses still do not benefit from this use. They deal with difficulties about the accessibility of data or the limited knowledge and resources to make use of the data. The use of open data involves stakeholders, staff, software providers and government actors (Zuiderwijk et al., 2015).

On the contrary, researchers determine barriers and challenges that disturb the use of open data. The barriers are categorized into ten categories. These categories are availability and access, findability, usability, understandability, quality, linking and combining data, comparability and compatibility, metadata, interaction with the data provider and opening and uploading (Zuiderwijk & Janssen, 2014). The barriers which are included in these categories are legislation, information quality, and technology, use and participation (Janssen et al., 2012). Other barriers are about technical issues, privacy or law (Conradie & Choenni, 2014). Challenges and problems could come up to the capability of users and application developers to identify the advantages related to open data. These challenges and problems are related to unfamiliar business idea in order to use data to develop new business, lack of technical readiness to use data sources due to complex data format or interfaces, weakness to generate suitable data sources for application goals, insufficient access of regional data sources for developing applications for local services, unclear licensing of open data, legal issues related to data that are not officially open by decision of owner, technical restrictions mentioned to data publishing platforms, warranty of quality and reliability of data, lack of local data and usefulness of open data (Jaakkola et al., 2014).

There is a need for education, experience from users, citizens and businesses and support from government to use open data (Pope & Greene, 2003). Statistical techniques are used for the collection, analysis and visualization of data. Knowledge about these techniques is limited. So, training is necessary to expand the capabilities of using these techniques (Janssen et al., 2012).

There is a number of dimensions which point out the significance of open data. These dimensions are related to legislative, political, social, economical, institutional, operational and technical aspects. A legislative dimension concentrates on freedom of information acts, open data policies, open government instructions, notes and state-

ments. A political dimension brings the importance of both political evolutions and political differentiation among countries. A social dimension examines the importance of cultural differentiation between countries and discrepancies in agendas related to the social advantages of opening data, such as transparency and accountability into focus. An economical dimension focuses on financial benefits which can be appeared with open data. An institutional dimension emphasizes the ways in which organizations allow and push the publication and adoption of open data. An operational dimension highlights the use of open data and the demand for being able to use open data. A technical dimension emphasizes the importance of open data technologies, open data platforms and open data substructures (Zuiderwijk & Janssen, 2014).

Hackathons

Governments aim to scrimmage citizens and developers who expand an application using open data to participate in contests and to explicate it through contests. By hosting these competitions, governments wish to inform citizens about the concernment and the use of open data while they are also supporting the expansion of new applications. Despite the rate of their popularity, contests and hackathons are a new phenomenon and researchers have not focused on their interest yet. More attention should be paid to these hackathons. Furthermore, researches which highlight the benefits of the contest or hackathon, for both sponsoring governments and hackathon participants are limited. These hackathons are frequently consolidated with prize money for participants and they typically inform, encourage and convince public of the use of open data and their value. Hackathons represent a specific challenge or topic (such as tourism), on which the sponsoring government intends to contribute to the creation of an application for citizens which will meet the market needs (Johnson & Robinson, 2014). Therefore, the most significant challenge of hosting a contest or a hackathon is to convince

developers to generate innovative ideas, which can be transformed to applications for the citizens. Hackathons include activities such as idea generation, software design, implementation and testing, service operation and monitoring (Juell-Skielse et al., 2014). Open data contests or hackathons have the same purpose, but in the first category of competitions developers create applications based on open data. Thus in this view the fact that it is the responsibility of governments to supply with free and easily open data is derived.

Participants can access data through references to data as provided in journal articles, newsletters or other publications, government or institutional announcements, data archives/repositories/systems, web search engines, directories or catalogs, social media, blogs as well as with direct requests to data providers (Schmidt et al., 2016). Especially, examples of open research data which are distributed as government statistics and industry records are GenBank, Protein Data Bank, Sloan Digital Sky Survey, World Data Centers, Global Biodiversity Information Facility, NASA Distributed, Active Archive Centers, International Virtual Observatory Alliance, Digital Earth, PubMedCentral and arXiv (Pasquetto et al., 2015).

Examples of motivations regard the participation in the contest are training, the fairness of the judgment system, the collaboration and new knowledge (Rosell et al., 2014). Fun and enjoyment, intellectual challenge, status and reputation, user need, professional and personal identity, autonomy, learning and skills development, money, extrinsic reciprocity, signaling and career concerns motivate developers to participate in the innovation competitions (Juell-Skielse et al., 2014). Motivations such as fun, learning and collaboration convince developers to generate ideas that include high market and technical uncertainties (Komssi et al., 2015).

Previous researches on what motivates the developers to participate in open data competitions, as well as on the benefits and challenges which are caused by the use of open data are limited. Furthermore, researches focus on factors that

affect nascent entrepreneurs' decision to create a startup but researchers in the field of open data and hackathons relative researches are limited.

Table 1 summarizes the motivations to take part in the competition, the sources for search open data, as well as the benefits and the barriers of the use of open data.

Examples of created services which are based on open data aim to improve the economy, transparency, society, education, citizen life, navigation and mobility, tourism, environment, security and religion (Foulonneau et al., 2014).

The findings of these surveys show that companies use open data for visualization in order to support management and decision making. Statistics and identification of trends are useful because managers can make more effectively decisions. The use of open data can support the prediction of future trends, too. Also, open data can be shared among businesses and other ac-

tors to co-create in service development process. The sharing of open data is an innovative and attractive way to improve services, generating new ideas and develop new applications and services. Furthermore, businesses can use open data to analyze customers' behaviour, preferences and future demands. Researchers have focused on studying how businesses can communicate with customers using Information Technology (Kitsios & Kamariotou, 2016). When businesses provide data to developers, they can implement applications which are based on customers' preferences. Thus, businesses have to communicate with customers and they have to think about how customers can provide these data. It is important for businesses to define why data should be opened both in their policies and their business models. Managers should support a culture for innovation and sharing of open data to gain the benefits of their use (Immonen et al., 2014).

Table 1. Description of the variables

Variables	Questions	References
Motivations to take part in the competition	Fun and Enjoyment	(Juell-Skielse et al., 2014)
	Intellectual Challenge	(Juell-Skielse et al., 2014)
	Status and Reputation	(Juell-Skielse et al., 2014)
	User Need	(Juell-Skielse et al., 2014)
	Professional and Personal Identity	(Juell-Skielse et al., 2014)
	Autonomy	(Juell-Skielse et al., 2014)
	Learning and Skills Development	(Juell-Skielse et al., 2014)
	Money	(Juell-Skielse et al., 2014)
	Reciprocity	(Juell-Skielse et al., 2014)
	Signaling and Career Concerns	(Juell-Skielse et al., 2014)
Sources for search open data	References to data as provided in journal articles	(Schmidt et al., 2016)
	Newsletters or other publications	(Schmidt et al., 2016)
	Government or institutional announcements	(Schmidt et al., 2016)
	Searching in specific data archives/repositories/systems	(Schmidt et al., 2016)
	Web search engines	(Schmidt et al., 2016)
	Directories or catalogs	(Schmidt et al., 2016)
	Social media	(Schmidt et al., 2016)
	Blogs	(Schmidt et al., 2016)
	Direct requests to data providers	(Schmidt et al., 2016)

continued on following page

Table 1. Continued

Variables	Questions	References
Benefits of the use of open data	More transparency	(Janssen et al., 2012)
	Democratic accountability	(Janssen et al., 2012)
	Creation of trust in government	(Janssen et al., 2012)
	Improvement of public policies	(Janssen et al., 2012)
	Fair comparison with other research results	(Janssen et al., 2012)
	Easier access to data and discovery of data	(Janssen et al., 2012)
	Creation of new data based on combining data	(Janssen et al., 2012)
	Sustainability of data (no data loss)	(Janssen et al., 2012)
	The ability to reuse data/not having to collect the same data again and counteracting unnecessary duplication and associated costs (also by other public institutions)	(Janssen et al., 2012)
	Availability of information for investors and companies	(Janssen et al., 2012)
	Optimization of administrative processes	(Janssen et al., 2012)
	New governmental services for citizens	(Janssen et al., 2012)
	New (innovative) social services	(Janssen et al., 2012)
	Development of new products and services	(Janssen et al., 2012)
	Improvement of citizen services	(Janssen et al., 2012)
	Contribution toward the improvement of processes, products, and/or services	(Janssen et al., 2012)
	Economic growth and stimulation of competitiveness	(Janssen et al., 2012)
	Stimulation of innovation	(Janssen et al., 2012)
Barriers of the use of open data	Emphasis of barriers and neglect of opportunities	(Janssen et al., 2012)
	Lack of ability to discover the appropriate data	(Janssen et al., 2012)
	Difficulty in searching and browsing due to no index or other means to ensure easy search for finding the right data	(Janssen et al., 2012)
	Lack of knowledge to make use of or to make sense of data	(Janssen et al., 2012)
	Lack of information	(Janssen et al., 2012)
	No information about the quality of the open data	(Janssen et al., 2012)
	Incomplete information, only part of the total picture shown or only a certain range	(Janssen et al., 2012)
	No license for using data	(Janssen et al., 2012)
	Data available in various forms	(Janssen et al., 2012)
	Data formats and datasets are too complex to handle and use easily	(Janssen et al., 2012)
	Lack of the necessary capability to use the information	(Janssen et al., 2012)
	No process for dealing with user input	(Janssen et al., 2012)
	Having to pay a fee for the data	(Janssen et al., 2012)
	Registration required before being able to download the data	(Janssen et al., 2012)
	Legacy systems that complicate the publicizing of data	(Janssen et al., 2012)
	No uniform policy for publicizing data	(Janssen et al., 2012)
	No resources to publicize data (especially small agencies)	(Janssen et al., 2012)

The results of a survey in 21 teams participated in the final of Travelhack 2013 show that participants were citizens who were interested in developing services, project teams representing businesses and startups which aim to generate businesses from applications. The motivational factors with the highest value were self explanatory, named; Fun and Enjoyment, Intrinsic Intellectual Challenge and Intrinsic Status and Reputation. Also, the majority of the teams planned to finalize the service. An important finding is that money was a weak motivational factor (Juell-Skielse et al., 2014).

Schmidt et al., (2016) provide the results of 1253 participants to the Belmont Forum's Open Data Survey. The results of this survey show that open data are important for research (82%) as well as supporting applications (51%). The majority of participants expressed that the quality of data, the low cost, the ability of reuse and the easy of accessibility were the main benefits using open data. On the other hand, the most significant barriers were the legal constraints, the loss of recognition and the desire to publish results before realizing data. Furthermore, participants discover data in journal articles, web search engines and specific data repositories.

Rosell et al., (2014) present the results of an internal hackathon at AT&T. They observed that the participants felt as entrepreneurs, learning new technologies and having the freedom to develop new applications. Organizers of this hackathon followed a cyclical process which indicates that hackathon gives the opportunity to developers to generate new ideas and expand them into platforms. This expansion is supported by the learning of new technologies which can be useful for the production of new services.

These findings conclude that current studies have started to explore issues related with the use of open data by businesses, governments and developers participating in innovation contests but there are still several unanswered issues.

FUTURE RESEARCH DIRECTIONS

Hackathons support only the first phase of the development of applications. Thus, the understanding of collaborative development of digital services and the support of new mechanisms for increasing the support of the later phases of digital service development are proposed to be further expanded. Moreover, further research should be implemented in providing guidelines to organizers of innovation contests to develop them better to meet participants' needs of specific open data market.

Several technologies, such as cloud computing, semantic web technologies and interoperable applications can be used to support the development of digital services based on open data. However, issues which concern about the owners of data, the payment policies and the security of private data are still unanswered. A type of public catalogue of available open data is necessary to provide details about the most demanded open data.

CONCLUSION

Open data provides new business opportunities, new types of business models and an ecosystem where actors use open data to develop new digital services. Although open data is a new trend, the interest of businesses is high and they should be followed to be competitive, businesses are not yet motivated to provide widely their own data.

In this chapter, many motivations and opportunities were identified for businesses and developers using open data. Also, obstacles limiting the usage of open data were determined. The participation of businesses and developers in hackathons is important because they will understand the significance of open data, the benefits which they will gain and they can co-operate to develop new digital services. The main stakeholders, involved in open data processes are data providers, open

data legislators, open data facilitators and many different kinds of open data users, such as citizens, researchers, journalists, developers, entrepreneurs and academics. Governments ask to engage citizens and developers who build an application using open data promoted and distributed through contests. By organizing these contests, governments hope to inform about the importance and the use of open data while they also encourage the development of new applications and startups. A lot of survey is still necessary to be done to bring under control the barriers and to examine how hackathons can be used to support the co-operation among developers, businesses and governments.

KEY TERMS AND DEFINITIONS

Actors of Open Data: Data providers, open data legislators, open data facilitators and many different kinds of open data users, such as citizens, researchers, journalists, developers, entrepreneurs and academics.

Barriers of Open Data: The barriers were categorized into ten categories. These categories are availability and access, findability, usability, understandability, quality, linking and combining data, comparability and compatibility, metadata, interaction with the data provider and opening and uploading.

Benefits of Open Data: Increased transparency, accountability, participation and self-empowerment of citizens to economic growth and stimulation of competitiveness and innovation.

Digital Innovation Contest: An event in which third party developers participate to develop and implement the most satisfying service prototype, for a particular aim, based on open data.

Hackathons: Hackathons are events where people come together in order to engage in creating and launching a new or finished application, which will solve citizens' problems.

Open Data Ecosystem: It displays the relationship among government, innovators and citizens, which is involved within the larger environment, such as the economy, legal system, and policy expertise.

Open Data: Open data can be defined as freely, accessible, online data, which are available and can be reused and they are provided under open access allowance so that the data can be reused without restrictions.

INTRODUCTION

With the rapid development of technology, there is an increasing demand for fuels. Natural gas is an environmentally friendly, renewable, and clean energy source. It is also the third largest proportion in energy structure throughout the world after coal and oil. The composition of the raw natural gas extracted from producing wells depends on the type, depth, and location of the underground deposit and the geology of the area. Natural gas consists primarily of methane as the prevailing element but it also contains considerable amounts of light and heavier hydrocarbons as well as contaminating compounds of CO_2 , N_2 , Hg, He, H_2S and etc. The presence of acid gases such as CO_2 and H_2S can cause corrosion of pipeline and equipment and they present a major safety risk. Also they reduce the energy content of the gas and affect the selling price of the natural gas. Further in Liquefied Natural Gas (LNG) processing plant, while cooling the natural gas to a very low temperature, the CO_2 can be frozen and block pipeline systems and cause transportation drawback. Consequently, natural gas produced at the wellhead must be processed, i.e., cleaned, before it can be safely delivered to the high-pressure, long-distance pipelines that transport the product to the consuming public.

The traditional method for CO_2 separation is amine scrubbing. Although high product yields

and purities can be obtained, the disadvantage of this method is its high energy consumption, especially during stripper, in combination with high liquid losses due to evaporation of the solvent in the stripper (Naim et al., 2012). In addition, as liquid and gas streams cannot be controlled independently the occurrence of flooding, foaming, channeling and entrainment of the absorption liquid also limits the process. Membrane technology is a promising method to replace the conventional absorption technology. It has a high energy efficiency, is easy to scale-up because of its modular design and it has a high area-to-volume ratio. A limitation can be found in the permeability-selectivity tradeoff relation. Gas-liquid membrane contactor (GLMC) combines the advantages of membrane technology with those of absorption liquid (Ze et al., 2014). In a GLMC the microporous membrane acts as a fixed interface between the feed gas and the absorption liquid without dispersing one phase into another and this decoupling of the gas and liquid phase prevents any momentum transfer occurring across the phase boundary. As a consequence, the operation problems and constraints take place in conventional absorption technology can be resolved. Further the employment of microporous membrane elucidates the permeability-selectivity tradeoff relation drawback challenged in membrane technology. The performance of GLMC as CO_2 absorber and stripper depend upon several

DOI: 10.4018/978-1-5225-2255-3.ch266

factors such as type of membrane, type of absorption liquid, module configurations and process parameters. Understanding the optimistic attributes of these factors on CO_2 separation performance of GLMC is vital important to develop the GLMC that gives the outstanding CO_2 absorption/stripping performance. The focus of this work is to illustrate the potential for the energy efficient and effective separation of CO_2/CH_4 gas mixture via lean solvent and regenerating of the rich solvent through absorption/stripping mechanism taking place in a hollow fiber GLMC process.

BACKGROUND

GLMCs have attracted great interest over the past decade as CO_2 absorber and stripper. In the absorber, CO_2 diffuses from the feed gas through the porous membrane and is then absorbed in the flowing liquid. Then this CO_2 rich liquid circulated from the absorber to the stripper membrane contactor module in which stripped CO_2 will be carried by sweep gas (Figure 1).

In the GLMC, gas and liquid flow on the different side of the microporous membrane and membrane acts only as a barrier between two phases without dispersing one phase to another. In general, when hydrophobic microporous membranes are used in membrane contactors, the gas-liquid interface is immobilized at the opening of the pores of microporous membrane by careful control of the pressure difference between the two phases. For applications in gas-liquid absorption/desorption, the driving force is based on the concentration gradient. The gas molecules to be separated diffuse from the concentrated phase to the gas liquid interface via the membranes pores then contacts the diluted phase on the other side. For instance, in the case of CO_2/CH_4 separation, as shown in Figure 2, CO_2 molecules diffuses from the feed gas side through the membrane and is then absorbed in the selective absorption liquid.

In GLMC the mass transfer process consists three steps in series: the transfer from one phase to the membrane surface, transfer within membrane pores and transfer from other phase interface to the bulk. Figure 3 shows the concentration

Figure 1. Membrane gas absorption/stripper process

Figure 2. CO₂ molecule transport through microporous membrane

profiles that are formed when species “i” is transferred from the gas phase to the liquid and if hydrophobic membranes are used. In order to describe this mass transfer process between two phases through porous membrane a resistance in series model based on film theory can be used. The resistances to the mass transfer encountered in both cases are those offered by the boundary layers and the membrane and can be drawn, as in Figure 4, by considering an electrical analogy.

As shown in the Figure 4, three resistances exist in the resistance in series model:

- Gas film resistance.
- Liquid film resistance.
- Membrane resistance.

A general expression used to calculate the flux of the species through the membrane is:

$$J = K_{ov}(C_1 - C_2) \quad [1]$$

with

$$\frac{1}{K_{ov}} = \frac{1}{k_G} \frac{d_o}{d_i} + \frac{1}{k_m} + \frac{1}{mEk_L} \quad [2]$$

hence

$$K_{ov} = f(k_G, k_m, k_L, m, E) \quad [3]$$

where J is flux. C_1 and C_2 are concentration of CO₂ in the two phases. K_{ov} is overall mass transfer coefficient. k_G , k_m and k_L are individual mass transfer coefficient of gas phase, membrane and liquid phase respectively. M is physical solubility and E is enhancement factor if any chemical reaction present.

Hence overall mass transfer coefficient in GLMC, be determined by three individual mass transfer coefficients, solubility and enhancement factor which in turn be influenced by so many factors. Firstly, membrane mass transfer coefficient influenced by so many membrane inherent properties such as membrane pore size, porosity and tortuosity which on the other hand controlled by adopted fabrication method. Further membrane mass transfer coefficient also subject to whether the membranes pores are gas filled (ideal non wetted mode) or liquid filled (non-preferred wetted mode). Next, the gas and liquid mass transfer coefficients as well depend in GLMC module configurations and adopted process parameters during separation process such as gas and liquid flow rates, temperature etc. Solubility and enhancement factor depends on the type of solvent used. So detail understanding of these properties is vital important for complete understanding of GLMC. Qi and Cussler were the first to propose the idea of CO₂ absorption by sodium hydroxide in a HFMC. Afterwards GLMC as CO₂ absorber

Figure 4. Resistance in series model

has been comprehensively studied by several researchers and exciting experimental and theoretical results have been reported (Ghasem et al., 2011, 2012a, 2012b, 2013, 2014). Currently, efficient and effective CO_2 stripping from liquid absorbents by using membrane contactor has become the target of many researchers in the field and few experimental results have been reported [Rahim et al., 2014, 2015].

MAIN FOCUS OF THE ARTICLE

The schematic diagram in Figure 5 shows the experimental setup used to study the potential of

custom made hollow fiber GLMC for separation of CO_2/CH_4 gas mixture via lean solvent and regeneration of the rich solvent. Homemade and characterized 28% PVDF hollow fiber membranes (Ghasem et al., 2012, 2013) were used to prepare the GLMC modules. Shell and tube type modules were constructed using Perspex tube as shell (transparent) and hollow fiber membranes as tubes. The details of the membrane contactor modules are given in Table 1. Firstly the CO_2 absorption (by using fresh absorption liquids) and stripping (by using manually CO_2 loaded absorption liquids) performance of GLMC was tested separately. Then the absorption experiments were conducted by recycling the absorption liquid several times with

and without the stripping between each recycle to investigate the potential of using GLMC for continuous mode operation.

To study the absorption performance 10/90 vol% CO₂/CH₄ gas mixture was applied to the shell side of the membrane contactor module at different gas inlet flow rate (10 to 100 ml/min) by using mass flow controllers (Alicat Scientific). Different 0.5 M aqueous solutions of primary (MEA), secondary (DEA), hindered (AMP) amines and amine salts (PG) were used as absorption liquid. The liquid feed stream supplied to lumen side of the module at variable flow rate of 10-40 ml/min by using peristaltic pump (Masterflex® L/S®). Also the liquid feed stream was heated for different temperatures; range from room temperature 20 °C to 60 °C by using feedback control heater (WiseStir®). Exit gas concentration was measured using gas chromatography (Shimadzu, Japan). Also the long term absorption performance of absorption liquids was examined by running absorption experiments for 200 minutes. Moreover for PG the ratio between potassium hydroxide and glycine were altered in order to study the effect of solution pH on absorption/stripping performance. Further the recyclability of absorption liquids were studied by recycling the absorption liquid from absorber module with and without stripping between each cycle.

To study the stripping performance the liquid feed stream either coming from the absorber module or manual CO₂ preloaded aqueous solutions (different initial CO₂ loading) were pumped to the stripping module. Pure nitrogen, as a sweep gas,

was made to flow through the module shell side at different gas inlet flow rate (100 to 600 ml/min) by using mass flow controllers (Alicat Scientific). The liquid feed stream supplied to lumen side of the module at variable flow rate of 10-50 ml/min by using peristaltic pump (Masterflex® L/S®). Also the liquid feed stream was heated for different temperatures, range from room temperature 25 °C to 90 °C by using feedback control heater (WiseStir®). A counter-current flow mode was applied for the gas and liquid phases. Variable pressure difference range from 0.01 to 0.05 MPa was applied between the liquid stream and gas stream by using control valve in order to avoid the formation of bubbles on the liquid side and to study the pressure effect. The system was in operation for 30 min to achieve a steady state condition before taking samples. The liquid phase CO₂ concentration at the inlet and outlet of the stripper module was measured by using double chemical titration method (described in the succeeding section), to determine stripping flux and efficiency. Also the sweep gas exit concentration was measured by using gas chromatography (Shimadzu, Japan) in order to make sure the titration results. The experimental CO₂ absorption/stripping efficiency was calculated as:

$$\eta(\%) = \left(\frac{v_i C_i - v_o C_o}{v_i C_i} \right) \times 100 \quad (4)$$

Where C_i and C_o (mol/m³) are the feed gas CO₂ concentration for absorption and liquid phase CO₂ concentration for stripping at the inlet and outlet of the membrane module respectively. v_i and v_o (m³/min) are the feed gas flow rate for absorption and liquid flow rate for stripping at the inlet and outlet of the membrane module respectively

The CO₂ absorption/stripping flux of the module can be calculated as:

$$J_{co_2} = \frac{(v_i C_i - v_o C_o)}{A_i} \quad (5)$$

where J_{co_2} (mol/m² s) is the CO₂ flux and A_i (m²) is inner surface of the hollow fiber membranes.

Measurement of CO₂ Loading in Liquid Sample

CO₂ concentration in the aqueous solution was determined by double chemical titration method (Seo et al., 1996). An excess amount of 1.0 M NaOH solution was added to the known amount of CO₂ rich liquid sample, converting dissolved CO₂ into the nonvolatile ionic species. Then an excess amount of 1.0 M BaCl₂ solution was added to the solution. The solution then stirred and heated for 3 hour at temperature of 70°C. Absorbed CO₂ precipitates as BaCO₃. The excess NaOH was titrated with 1.0 M HCl solution using phenolphthalein as the indicator. After this titration, using Methyl Orange as the indicator, HCl was added to measure the amount of BaCO₃. The volume of HCl added to neutralize the basic species in the solution was used to calculate the CO₂ loading.

The CO₂ loading was calculated according to the following equation:

$$\alpha = \frac{v_{HCl}}{2 \times v_{sample}} \quad (6)$$

where α = CO₂ loading in mol of CO₂/volume of solution, v_{HCl} = volume of HCl request to neutral-

ize the BaCO₃ in ml, v_{sample} = volume of sample taken for analysis in ml.

SOLUTIONS AND RECOMMENDATIONS

The potential of custom made hollow fiber GLMC for separation of CO₂/CH₄ gas mixture via lean solvent and regeneration of the rich solvent was tested by using different aqueous solutions of primary (MEA), secondary (DEA), hindered (AMP) amines and amine salts (PG) as absorption liquids. The experimental results proved GLMC is promising energy efficient and effective alternative for conventional CO₂ absorption/stripping technology and the type of absorption liquid and operating parameters plays a vital role in eventual absorption/stripping performance given away by GLMC.

CO₂ Absorption Performance of GLMC

The CO₂ absorption experiments in GLMC revealed the absorption performance order of studied absorbent liquids is PG>MEA> AMP>DEA> regardless of operating conditions adopted (Figure 6). The aqueous amine-based solutions are usu-

ally adopted CO_2 absorption liquids and MEA is the most commonly used amongst them. The structures of alkanolamines include primary, secondary, ternary amines containing at least one OH and amine group such as MEA, DEA and MDEA. The reactivity of amines to CO_2 follows the order primary, secondary and ternary amines. So as obtained MEA has greater absorption performance than the DEA. In addition to these amines, the steric hindrance amines such as AMP also proposed by several researchers. This is because that the steric character reduces the stability of the formed carbamate and easy regenerate the solution. The absorption performance of AMP is better than the DEA as shown in figures. Amino acid salts (AAS) aqueous solutions attract great research interest in recent years as CO_2 absorbent liquid in GLMC because of its prominent characters such as their better affinities towards CO_2 than alkanolamines and their high surface tension because of its ionic nature. Hence mostly used PG absorption performance was compared with other absorbent liquids and its absorption performance was greater than the MEA aqueous solutions. As well even after 8 hours long run the PG did not wet the membrane. Whereas the amine solutions cause membrane wetting averagely after five six

hours of continuous running, this is due to its low surface tension.

Moreover from the absorption experiments it was observed the gas flow rate have a significant effect on CO_2 absorption performance in GLMC. Although as shown in Figure 6 the CO_2 absorption flux increased with gas flow rate the CO_2 removal efficiency decreased with increased gas flow rate. For instance for PG the removal efficiency reduced from 99% to 94% with the increased of gas flow rate from 10 ml/min to 100 ml/min. This can be attributed to decrease in contact time and increase in driving force for mass transfer. Increasing the gas flow rate decreases the residence time of the gas phase in the membrane contactor and hence contact time of the gas phase with liquid. On the other hand the increase in the gas velocity results in the reduction of the boundary layer and the improvement of the total mass-transfer rate. Further it was observed for any absorption liquid the CO_2 absorption performance in GLMC could be enhanced by high liquid flow rates. This enhancement in absorption performance was significant for the absorption liquids which have poor absorption performance than the absorption liquids which have good absorption performance. For PG the removal efficiency increased only by

Figure 6. CO_2 absorption performance of various absorption liquids in GLMC (0.5M aqueous solutions at room temperature flow in lumen side at 10 ml/min; gas mixture 9% CO_2 /91% CH_4 flows in shell side)

3.3%, whereas for DEA the removal efficiency increased by 17% with increase of liquid flow rate from 10 ml/min to 50 ml/min. This is attributed to higher liquid velocity leads to a lower CO_2 concentration in the liquid phase, which in turn results in a higher CO_2 concentration gradient between gas and liquid phase phases. Also increasing the liquid velocity turns the fluid flow form laminar to turbulent this reduces the liquid phase boundary layer.

The effect of temperature on CO_2 absorption performance in GLMC is attributed to collective effect of solubility (physical absorption), chemical reaction (chemical absorption), diffusion and evaporation of absorbent. Further increase in temperature would decrease the viscosity of the solution which is favorable character of GLMC absorbent liquid. It is well known the favored chemical reaction rate and diffusion rate with temperature would enhance the absorption performance. While decrease in CO_2 solubility and an increase in evaporation of absorbent (wetting) with temperature would reduce the absorption performance. Experimentally it was observed MEA and shows no any significant effect of temperature on absorption performance contrary to the results obtained with AMP and DEA. This may be due to for MEA and PG the favored chemical reaction and diffusion with temperature were compensated by the reduced solubility. Also these absorbent have good reactivity even at room temperature (around 95% removal), so the enrichment in absorption performance with temperature was not highlighted. Whereas for AMP and DEA the favored effect of temperature on chemical reaction and diffusion were higher than the reduced effect temperature on CO_2 solubility and so the enrichment in absorption performance with temperature was significant. However all solvents shows some flattening off at elevated temperatures. Because the wetting caused by elevated temperature cannot be neglected in long term operation. Further the thermal degradation of membrane material also should be considered. So, solvent temperature is

a crucial factor to be controlled very carefully for long term operation performance.

CO_2 Stripping Performance of GLMC

CO_2 stripping performance of PVDF hollow fiber GLMC was compared between primary (MEA), secondary (DEA), hindered (AMP) amines and amine salts (PG). The liquid solutions were manually preloaded with CO_2 for saturation level in order to obtain higher CO_2 flux for comparing purposes. In terms of regeneration AMP and PG perform well as absorbent liquid comparing to MEA and DEA. The results in Figure 7 show the effect of different aqueous solution on stripping flux as function of temperature. The regeneration energy of the absorbents was directly related with the heat of reaction and showed higher values when the binding force between amines and CO_2 molecules was larger. Therefore, absorbents that formed carbamate required larger quantities of heat, and the absorption heats of the MEA and DEA were higher than those of AMP and PG. So AMP and PG shows better stripping performance compare to MEA and DEA. Regardless of type of solvent the CO_2 stripping flux and efficiency increases with temperature rapidly. Because as the reaction rate increases with temperature, the formation of carbamate, which is the final product of CO_2 reaction, become unstable and the energy consumed in regeneration become smaller.

The studies on sweep gas flow rates exposed the gas flow rate have no any significant effect on stripping flux and efficiency regardless of type of solvent. However, when operating at high rich solution temperature, the low sweep gas flow rate, allow the vapor molecules to easily enter through the pores and wet the membrane. This reduces the effective long term operation of the membrane contactor module. So, moderate sweep gas flow rate gives better performance comparing to low sweep gas flow rate. Liquid flow rate shows some notable criteria on CO_2 stripping flux and efficiency. At low temperatures the increase in

Figure 7. Effect of liquid phase temperature on CO_2 stripping flux for four different solvents (saturation initial CO_2 loading, $v_l = 50 \text{ ml/min}$, $v_g = 600 \text{ ml/min}$ and $P_l - P_g = 0.5 \times 10^5 \text{ Pa}$)

liquid flow rate reduces the stripping efficiency. In contrast at high temperature the increase in liquid flow rate increases the stripping efficiency. Two phenomenon govern the stripping efficiency. The residence time (contact time between gas and liquid phase) and liquid phase boundary layer thickness. At low temperature contact time overtaken by the boundary layer thickness. Lower liquid velocity tend to higher residence time, which lets dissolved CO_2 to shift to gas-liquid interface and results in increasing the driving force of mass transfer. In contrast at high temperature due to low solubility more CO_2 end to be released. So rather than residence time boundary layer thickness is important. Because the liquid flow rate reduces the boundary layer thickness and increase the mass transfer coefficient, at high temperature high flow rates gives the high removal efficiency.

The liquid pressure also has great influence in the stripping performance. The considerable increase in CO_2 flux with liquid pressure can be attributed to the increase in driving force for desorption as a result of an increase in CO_2 concentration. Many researchers proved the CO_2 absorption flux increase drastically with gas phase pressure. So vice versa by increasing the liquid side

pressure the CO_2 desorption flux can be increased. But, even though, hydrophobic PVDF hollow fiber membrane can resist wetting, applying higher pressure in the liquid side can gradually cause wetting. It is well known that partial wetting of membrane can increase mass transfer resistance significantly. So the liquid side pressure should be maintained below the break through pressure.

The effect of absorption liquid pH on CO_2 absorption/stripping performance in gas liquid membrane contactor module was investigated by using asymmetric solutions of PG (i.e. solutions containing different molar amounts of amino acid (glycine) and base (potassium hydroxide)). At lower pH the CO_2 reaction equilibrium shifts towards the release of CO_2 enhancing the partial pressure of CO_2 . So higher molar ratios of amino acid shows better stripping and reduced absorption performance (Figure 8). Subsequently in continuous operation of absorption and followed up by stripping, the stripping performance was controlled by reduced absorption performance because of resultant low initial CO_2 concentrations. Hence for the net effect the molar ratio has to be optimized to achieve both good absorption and subsequent stripping performance.

Figure 8. Effect of different asymmetric solutions on overall efficiency

FUTURE RESEARCH DIRECTIONS

GLMC due to attested several advantages has become the promising alternative for conventional CO₂ absorption/stripping process. Although the GLMC for CO₂ separation has been extensively studied there is still a long way ahead before this technique to completely replace the existing CO₂ separation technology. The main hitch is long term stability of GLMC absorption process due to membrane wetting. The key is employing surface modified super hydrophobic membranes and high surface tension absorption liquids in GLMC absorption/stripping processes. Currently, various techniques such as surface grafting, bore filling grafting, coating/interfacial polymerization and in-situ polymerization are being investigated to improve the surface hydrophobicity. Some works are going on using ionic liquid membranes in GLMC applications. Further as a consequences of seek out for new absorption liquids that not only have high surface tension but also can be regenerable in efficient way, AAS and ionic liquids have attracted great research interest. Most importantly AASs have favorable biodegradation properties,

which make the disposal of these solvents easier and with lower environmental impacts. In spite of all these work still the membrane wetting at elevated temperatures is arguing. Moreover, despite the fact that solvent regeneration is responsible for the major cost component in gas separation processes due to energy consumption, the studies on CO₂ stripping using GLMC have started recently and there are only few reports documented in the open literature. Hence future research directions should focus on super hydrophobic membranes, absorption liquids that can be regenerated in an energy efficient way and eventually suitable membrane-absorbent combination, therefore, GLMC will thrive as a perfectly energy efficient and effective CO₂ absorption/stripping technology, which can replace the current CO₂ separation technology completely.

CONCLUSION

The experimental results proved GLMC is promising energy efficient and effective alternative for conventional CO₂ absorption/stripping technology

and the type of absorption liquid and operating parameters plays a vital role in eventual absorption/stripping performance given away by GLMC. Studied AAS (PG) shows both good absorption and stripping performance. The gas flow rate has a significant effect on CO₂ absorption performance where as it has no effect in stripping performance. Further the CO₂ absorption performance in GLMC could be enhanced by high liquid flow rates. This enhancement was significant for the absorption liquids which have poor absorption performance than the absorption liquids which have good absorption performance. In contrast, the stripping performance enhancement with liquid flow rate depends on liquid temperature. Because the gas-liquid contact time was a key factor to enhance the stripping flux at low temperature while liquid phase boundary layer thickness and associated mass transfer resistance is important at elevated temperature. So by controlling the liquid phase velocity and the length of module at low temperature better stripping performance can be achieved. The effect of liquid temperature on absorption performance in GLMC is not straightforward. Since the liquid temperature cooperatively influence the several factors which determines the absorption performance positively and negatively, it should be handled in care depending on the system used. However by increasing the rich solution temperature the stripping performance can be improved preferably. To improve the stripping performance enhanced CO₂ desorption (based on pH-shift) was studied. In this study the pH values were changed by using asymmetric solutions of PG. Lower pH shifts the reaction equilibrium towards the release of CO₂ and shows better stripping and reduced absorption performance. Thus for the net effect the molar ratio has to be optimized to achieve both good absorption and subsequent stripping performance.

KEY TERMS AND DEFINITIONS

AASS: Amino acid salt solution. Chemical solvent derived by mixing amino acid and alkaline hydroxides.

CO₂ Absorption: Operation used in removing acid gas from other gases using liquid solvent.

CO₂ Stripping: Operation used in removing absorbed acid gas from absorbent liquid.

GLMC: Gas Liquid membrane contactor. A device that have bundle of fibers enclosed on a shell in which gas and liquid flow without dispersing with each other.

Hydrophobic: The not-affinity to water.

Natural Gas: Gas consists with more than seventy percent methane.

PVDF: Polyvinylidene fluoride, polymer used in fabrication.

Wetting: Membrane pores filled with liquid instead of gas.

E

Enhancing the Resiliency of Smart Grid Monitoring and Control

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

Smart grid is one of the hottest research areas in recent years. The development of smart grid is partially driven by the fact that the traditional data communication infrastructure for electric power grid can no longer meet the needs of new developments (Wang, Xu, & Khanna, 2011):

- The recent deregulation would allow many independent parties to enter the utility industry by offering alternative channels for electric power generation, distribution, and trade. This inevitably demands timely, reliable and secure information exchanges among these parties (Bose, 2005).
- The current data communication infrastructure lacks the support for large-scale real-time coordination among different electric power grid health monitoring and control systems, which could have prevented the 2003 massive blackout incident in North America (Birman et al., 2005).
- The use of modern computer networking technology could also revolutionize the everyday electric power grid operations, as shown by the huge benefits of substation automation and the use of Phasor Measurement Units (PMUs) for electric power grid health monitoring (Melliopoulos, 2007).

However, the openness and the ease of information sharing and cooperation brought by smart grid also increased the likelihood of cyber attacks on the electric power grid, as demonstrated

recently by an experiment conducted by the US Department of Energy's Idaho Lab (CNN, 2007). To address such vulnerability, intrusion detection and intrusion tolerance techniques must be used to enhance the current and future data communication infrastructure for the electric power grid. Byzantine fault tolerance is a fundamental technique to achieve the objective (Castro & Liskov, 2002; Zhao, 2014a).

In this chapter, we focus our discussions on the security and reliability of smart grid health monitoring and control. We elaborate in detail the need for Byzantine fault tolerance and the challenges of applying Byzantine fault tolerance into this problem domain. In particular, we investigate experimentally the feasibility of using such sophisticated technology to meet potentially very stringent real-time requirement for the health monitoring and control of smart grid, while ensuring high degree of reliability and security of the system.

BACKGROUND

A Byzantine faulty process may behave arbitrarily. In particular, it may disseminate conflicting information to different components of a system, which constitutes a serious threat to the integrity of a system (Lamport, Shostak, & Pease, 1982). Because a Byzantine faulty process may also choose not to send a message, or refuse to respond to requests, it can exhibit crash fault behavior as well. Consider the scenario that multiple PMUs periodically report their measurement results to a controller for electric power grid health monitor-

ing. When it detects an abnormality, the controller may wish to issue specific control instructions to the actuating devices, such as Intelligent Electronic Devices (IEDs) (Hossenlopp, 2007) located at the same substation as those PMUs to alleviate the problem. Due to the critical role played by the controller, it must be replicated to ensure high availability. Otherwise, the controller would become a single-point of failure. The main components and their interactions are illustrated in Figure 1.

However, the controller replicas, the PMUs, and the IEDs, might be compromised under cyber attacks. Consider the following two scenarios:

- A Byzantine faulty PMU could potentially send inconsistent data to different controller replicas. Without proper coordination among the controller replicas, the state of the replicas might diverge in the former case, which would lead to inconsistent decisions among the replicas.

- A compromised controller replica could send conflicting commands to different IEDs. Without a sound mechanism at each IED, a malicious command might be executed in the latter case, which could lead to the destruction of a generator or a transmission line, as reported by CNN (2007).

Byzantine fault tolerance (BFT) refers to the capability of a system to tolerate Byzantine faults (Lamport, Shostak, & Pease, 1982). If BFT is used, the cyber attacks illustrated above could be defeated provided that the number of compromised controller replicas, f , is below a threshold, and the number of non-faulty PMUs and IEDs are sufficient for the normal operation of the substation. For the client-server system shown in Figure 1, BFT can be achieved by using $3f + 1$ replicas to tolerate up to f faulty replicas and by ensuring all non-faulty replicas to execute the same set of requests in the same order. The latter means that the server replicas must reach an agreement on the set of requests and their relative ordering

Figure 1. The interaction of substation devices (PUMs and IEDs) and the controller replicas

despite the presence of Byzantine faulty replicas and clients. Such an agreement is often referred to as a Byzantine agreement (Lamport, Shostak, & Pease, 1982). The Byzantine agreement among the replicas ensures that a faulty client (i.e., a PMU) cannot cause the divergence of the state of non-faulty controller replicas. Furthermore, a Byzantine agreement must be reached among all non-faulty replicas on each command issued by the controller for reasons to be explained in the next section. Before an IED can accept the command, it must wait until it has collected at least $f + 1$ identical command from different replicas.

We should note that Byzantine fault tolerance has been a hot research area in many other areas, such as Web services (Merideth et al., 2005; Zhao, 2009) and data storage systems (Rhea et al., 2003). Even though the works are in a different context, many insights are useful for BFT controls in electric power grid applications. In particular, the mechanisms designed to cope with the interaction of a replicated object and the un-replicated external entities reported in (Merideth et al., 2005) have been partially incorporated in this work.

BYZANTINE FAULT TOLERANT MONITORING AND CONTROL MECHANISMS

In this work, we choose to use PBFT, a well-known Byzantine agreement algorithm developed by Castro and Liskov (2002). The PBFT algorithm is designed to support client-server applications running in an asynchronous distributed environment with the Byzantine fault model. The implementation of the algorithm contains two parts. At the client side, a lightweight library is in charge of sending the client's request to the primary replica, retransmitting the request to all server replicas on the expiration of a retransmission timer (to cope with the primary faults and network faults), and collecting and voting on the corresponding replies. The main PBFT algorithm is executed at the server side by a set of $3f + 1$ replicas to toler-

ate up to f faulty replicas. One of the replicas is designated as the primary while the remaining are backups. Furthermore, all messages are protected by a digital signature, or an authenticator (Castro & Liskov, 2002) so that a faulty replica or client cannot tamper with the messages and cannot impersonate as another non-faulty replica or client.

The normal operation of the (server-side) PBFT algorithm involves three phases: pre-prepare, prepare, and commit. In the beginning of the pre-prepare phase, the primary multicasts a pre-prepare message containing the client's request, the current view number and a sequence number assigned to the request to all backups. A backup verifies the request message and the ordering information. If the backup accepts the message, it multicasts to all other replicas a prepare message containing the ordering information and the digest of the request being ordered. This starts the prepare phase. A replica waits until it has collected $2f$ prepare messages from different replicas (including the message it has sent if it is a backup) that match the pre-prepare message before it multicasts a commit message to other replicas, which starts the commit phase. The commit phase ends when a replica has received $2f$ matching commit messages from other replicas. At this point, the request message has been totally ordered and it is ready to be delivered to the server application if all previous requests have already been delivered. If the primary or the client is faulty, the Byzantine agreement on the ordering of a request might not be reached, in which case, a new view is initiated, triggered by a timeout on the current message being ordered. A different primary is designated in a round-robin fashion for each new view installed.

For electric power grid health monitoring and control, however, the above BFT algorithm cannot be used directly, because normally the controller replicas collect input from the PMUs and the control commands are issued to IEDs. Furthermore, the updates from PMUs are one-way messages in that the PMUs normally do not wait for an explicit response from the controller. On the other hand, IEDs are acting as the server role

when it receives the control commands from the controller replicas. Table 1 provides a summary of the actions taken by the controller replicas in response to receiving a report from a PMU and to sending of a command to an IED.

On collecting PMU data, the controller replicas engage in a Byzantine agreement for each input message as usual, as shown in Figure 2. However, the message delivery procedure must be modified. When a replica reaches a Byzantine agreement on the message, and it has delivered all previously ordered messages, it invokes the callback function provided by the controller to deliver this message. On the return of the up-call, no message is sent back to the PMU.

Upon issuing a control command, a controller replica does not directly send the command to the target IED. Instead, a round of Byzantine agreement on the command message is conducted, as shown in Figure 3. The procedure is very similar to that of PMU input message ordering, except that the pre-prepare message is triggered by the issuing of a control command rather than the receiving of a client's request, and the command is sent to the target IED when the Byzantine agreement is reached, instead of delivering a request. As mentioned in the previous Section, the target IED

must not accept a control command immediately because the command might have been sent by a faulty controller replica. By waiting until it has received $f + 1$ identical command from different controller replicas, it can guarantee that at least one of them is sent by a non-faulty replica, because at most f replicas can be faulty according to our assumption.

If the replicas operate completely deterministically and in lock-step, the round of Byzantine agreement for the commands to the IEDs is not necessary. However, it is virtually impossible to guarantee lock-stepped execution of the replicas across a network. If the control command contains information such as the time to execute the command, the commands issued by different replicas would contain different timestamps, which would make it impossible for the IEDs to authenticate and compare the commands for acceptance. Therefore, in general, it is necessary for the replicas to reach an agreement on the command to be issued to the IEDs. Here, we assume that a backup replica is able to verify if the command proposed by the primary is valid. A backup would initiate a view change if it deems that the command from the primary is invalid. If a backup replica cannot verify the command issued by the primary,

Figure 2. Normal operation of the BFT algorithm for PMU report handling

Figure 3. Byzantine agreement (normal operation) on the control command at the controller replicas and the acceptance of the command at an IED

Table 1. A summary of the actions taken by the controller replicas in response to receiving a report from a PMU and to sending of a command to an IED

Event	Actions Taken
On receiving a report from PMU	Byzantine agreement on the report No message is sent back to PMU
On sending of a command to IED	Byzantine agreement on the command prior to sending IED must collect $f+1$ consistent commands from different replicas

more sophisticated mechanisms must be used, as reported in (Zhang et al., 2011).

EXPERIMENTAL ASSESSMENT

The implementation of our Byzantine fault tolerance framework is based on the PBFT library developed by Castro and Liskov (2002). We incorporated the changes necessary for electric power grid monitoring and control as mentioned in the previous Section.

The test-bed consists of 12 PCs in a local-area network (LAN) connected by a 100Mbps Ethernet. Four of the PCs in the LAN are equipped

with Pentium IV 2.8GHz processors and 256MB memory, and the remaining PCs in the LAN each has a single Pentium III 1GHz processor. All PCs on the LAN run the Red Hat 8.0 Linux. The remote PC has one Pentium IV 3.2GHz processor running CentOS 4.5 Linux.

The main objective of the performance evaluation is to assess whether or not the Byzantine fault tolerance mechanisms are efficient enough to meet the real-time communication requirement for power grid health monitoring and control. Consequently, we characterize the response time and jitter of the Byzantine fault tolerant system.

The test application simulates the electric power grid health monitoring and control scenario

as shown in Figure 1. The controller is replicated in the 4 Pentium IV PCs (one replica per PC) and the PMUs and IEDs are run on the remaining 8 Pentium III PCs (a pair of PMU and IED on each PC). During the experiments, up to 8 concurrent PMU-IED pairs are used.

A PMU (as the client) periodically reports its measured data to the replicated controller according to the IEEE 1344 standard. Upon each PMU message received, the controller replicas generate a command and send it to the corresponding IED (collocated on the same node as the reporting PMU). Note that this is done purely for the purpose of performance characterization and might not match the practical usage scenarios. The payload of each PMU report is 14 bytes long. The payload of each control command is set to 128 bytes long.

Furthermore, the PCs in our test-bed are not equipped with high-resolution GPS devices, preventing us from directly measuring one-way latencies for PMU reports and control command notifications. Instead, we measure the round-trip time from the sending of a PMU report to the receiving of a command in response to the report at a collocated IED.

To gain insight on the jitters of networking and Byzantine agreement processing delays, we

measure the intervals between two consecutive sending of PMU reports at each PMU and the intervals of consecutive deliveries of the PMU reports at each controller replica, and compare the probability density functions (PDFs) of the sending intervals and the delivery intervals. The PDFs provide a much more detailed and accurate picture on the predictability of the arrival rate of the PMU reports at the controller replicas than using the mean values and standard deviations. For similar reasons, the PDF is used to capture and present the round-trip times. In each run, 10,000 samples are taken.

Figure 4 shows the experimental results under the normal operation condition. The number of concurrent PMU-IED pairs varies from 1 to 8. The PDFs for the sending intervals measured at the PMUs are shown in Figure 4(a). The interval between two consecutive sending is controlled by the `nanosleep()` API provided by Linux. Even though the target interval is 10 milliseconds, the actual intervals vary slightly (with peak value of about 11.6 milliseconds). If there is no jitter in networking and Byzantine agreement processing, the PDFs of the delivery intervals measured at the controller replicas should be identical to those of the sending intervals. The PDFs of the

Figure 4. The measured PDFs with various number of PMU-IED pairs. (a) The report-sending interval at the PMU. (b) The delivery interval at the controller replicas. (c) The round-trip time from sending a PMU report and the receiving of a control command

delivery intervals shown in Figure 4(b) indicate that there is noticeable jitter. However, the jitter is small enough to sustain a 60Hz PMU sampling rate for all scenarios tested (up to 8 concurrent PMU-IED pairs), which is often regarded as the most demanding SCADA requirement (Johnston, 2005). Furthermore, Figure 4(c) shows that the round-trip time is in the sub- millisecond range, again for all scenarios measured, which is more than adequate to ensure urgent sensing data delivered and control command acted upon.

When the primary controller replica is faulty, it may take a significant amount of time (e.g., 2 seconds) for a view change to complete. During this period of time, the controller is basically out-of-service. To address this issue, the controller should periodically send contingency control commands to the IEDs. If an IED does not receive a control command in time, it should resort to the contingency command. We emphasize that this situation, even though not desirable, is far better than the IED executing a command sent by a malicious controller, which can lead to the destruction of critical components of the power grid.

FUTURE RESEARCH DIRECTIONS

There is a large body of research work on how to restructure the current data communication infrastructure for electric power grid, such as (Zhang, Wang, & Xiang, 2015; Birman et al., 2005; Bose, 2005; Hossenlopp, 2007; Melliopoulos, 2007). The SCADA security issues have also attracted worldwide attention (<http://sandia.gov/scada/>). However, the work that targets both the security and reliability aspects of the infrastructure is rarely seen. Our work appears to be the first to assess if it is possible to apply the Byzantine fault tolerance technology for electric power grid health monitoring and control. We plan to carry out more in-depth investigations. In particular, the performance of the BFT technology in the wide-area network environment should be carefully evaluated. Furthermore, we also plan to explore

context-ware and adaptive fault tolerance (Buys et al., 2011) to improve the performance and robustness of our framework. Another research direction is to improve the performance of the proposed framework by adapting our replication protocol specific for SCADA interactions. We call this line of research application-aware Byzantine fault tolerance (Zhao, 2014a; Zhao, 2014b).

The importance of stable sampling rate for networked sensing and control is addressed in (Liberatore, 2006). In (Liberatore, 2006), Liberatore proposed a playback-based method to increase the predictability of the sampling rate. This method seems to be a good candidate to be integrated with the proposed framework to address the potential jittering problem in the wide-area networks.

CONCLUSION

In this chapter, we presented the justification and a feasibility study of applying the Byzantine fault tolerance technology to electric power grid health monitoring. We proposed and implemented the BFT mechanisms needed to handle the PMU data reporting and control commands issuing to the IEDs. We carried out an empirical study to assess the feasibility of using the BFT technology for reliable and secure electric power grid health monitoring and control. We show that under the LAN environment, the overhead and jitter introduced by the BFT mechanisms are negligible, and consequently, Byzantine fault tolerance could readily be used to improve the security and reliability of electric power grid monitoring and control while meeting the stringent real-time communication requirement for SCADA operations.

While the brief out-of-service time (typically in 1-2 seconds) during a view change can be a concern for electric power grid health monitoring and control, additional mechanism, such as the playback scheme proposed in (Liberatore, 2006) could be used to alleviate the problem. In any case, the BFT sensing and control ensures that a PMU report from a compromised PMU

cannot cause the state divergence of the correct controller replica, and a control command from a compromised control replica is never accepted by a correct actuating device such as an IED.

KEY TERMS AND DEFINITIONS

Byzantine Fault Tolerance: It refers to the capability of a system to tolerate Byzantine faults.

Intelligent Electronic Device (IED): It is an actuating device that is capable of receiving commands from a controller. Example IEDs include protective relaying devices, and voltage regulators.

Jitter: It refers to the deviation from the periodicity of a sequence of events or signals.

Normal Operation: It refers to the operation of an algorithm during a period that either there is no fault, or the faults do not disrupt its operation. For example, when a backup replica crashes, the PBFT algorithm would still operate as normal.

Phasor Measurement Unit (PMU): It is a device that measures the electrical waves in an electric power grid. The measurements must be synchronized with a global clock, such as a GPS.

Sampling Rate: It is defined as the number of samples taken per unit of time.

SCADA: It is short for Supervisory Control and Data Acquisition. It is a type of industrial control system that monitor and control industrial processes that exist physically.

View Change: It refers to the configuration change of the group of replicas that engage in Byzantine fault tolerance. When the primary is suspected of being faulty, a new view is initiated so that a different replica is elected as the primary for the new view.

E-Waste, Chemical Toxicity, and Legislation in India

Prashant Mehta

National Law University Jodhpur, India

INTRODUCTION

The industrial revolution was a period of dynamic change and dramatic innovation in the history of human society (Ayers, 1999). Across the world, societies are constantly reinventing to manage revolutionary changes that have radically transformed the lifestyle of people. Some of these changes are subtle and barely noticeable, while other changes are blatant and abrupt, like advances in Information and Communication Technology (ICT) and widespread use of Electrical and Electronics Equipment (EEE), which has made human civilization to grow in a more efficient manner.

Following economic liberalization in 1991, the Indian ICT industry has been one of the major drivers of economic progress both in terms of volume and applications. It has assumed the role of providing a forceful leverage to the socio, economic, and technological growth of a developing society (Joseph, 2007). However consumption and production processes of these complex electronic devices are unsustainable, pose a serious challenge to environment and human health, making e-waste one of the largest growing waste streams (Lundgren, 2012a). With waste market getting increasingly global, such waste is illegally exported to crude e-waste recycling hotspots in Asian countries, such as China, India, and Pakistan, and in some African countries, like Ghana and Nigeria (Castillo, 2011). Such illegal trade in e-waste is camouflaged and conducted under the pretext of obtaining 'reusable' equipment or 'donations' from developed nations.

E-waste comprises of ICT and EEE products that are not fit for their originally intended use. It includes computers, its accessories (monitors,

printers, keyboards, and central processing units), typewriters, mobile phones and chargers, remotes, compact discs, headphones, batteries, LCD/Plasma TVs, air conditioners, refrigerators, and other household appliances (Lalchandani, 2010). The increasing 'market penetration' in the developing countries, 'replacement market' in the developed countries (Borthakur & Sinha, 2013), coupled with rapid developments, innovation, miniaturization, and replacement resulted into higher rate of obsolescence of electronics products. It is estimated that in 2014 world-wide 41.8 million metric tonnes (Mt) e-waste was generated and most of it was not collected and treated in environmentally sound manner (Baldé, Wang, Kuehr, & Huisman, 2015). Most of this either end up with municipal waste in landfills or unauthorized recycling yard (Greenpeace Press Report, 2008).

As noted by UNEP in 2005, "Every year, 20 to 50 million tonnes of e-waste is generated world-wide, which could bring serious risks to human health and the environment" (Schwarzer, Giuliani, Kluser, & Peduzzi, 2005). Even though there is no clear data on the quantity of e-waste generated and disposed of each year in India, it is estimated 70 percent of e-waste handled in India is imported. It also estimates that between the years of 2007-2020, domestic television e-waste will double, computer e-waste is expected to increase five-fold, while cell phones will increase eighteen times (Disabled World, 2015). Thus knowledge society of 21st century is creating its own toxic footprint which is most debated issue amongst the environmentalists, environment regulators, world-wide environment forums, governmental, and non-governmental agencies, and policy makers.

DOI: 10.4018/978-1-5225-2255-3.ch268

BACKGROUND OF STUDY

Solid waste management, which is already a mammoth task in India, is becoming more complicated by the invasion of e-waste, which has complex characteristics as it differs chemically and physically from urban or industrial waste. Each wave of technology creates a set of waste previously unknown by humans (Sikdar & Vaniya, 2014) making e-waste management a big issue in both developed and developing countries.

The current practices of e-waste management in developing countries suffer from a many drawbacks such as informal recycling, inadequate legislation, low public awareness of the hazardous nature of e-waste, use of obsolete methods, and inadequate emphasis on the employee's protection (Cobbing, 2008), is jeopardizing people's health and environment (Smith, Sonnenfeld, & Naguib Pellow, 2006a).

Having reviewed literature from various other studies conducted in India and abroad, and understanding the magnitude of this problem, it is time for India to critically review its management of e-waste, to work towards a strategy to create the necessary infrastructure, and mechanisms to support sustainable and environmentally friendly e-waste management besides sensitizing consumers, waste recyclers, and future decision makers on issues like e-waste characteristics, its trans-boundary movement recycling technology, social, and environmental considerations, and toxic effect on health.

DEFINITION OF E-WASTE

Even though there is no standard definition for e-waste, some of the reported definitions of e-waste in literature are mentioned below:

According to the Basel Convention, "Wastes are substances or objects, which are disposed of or are intended to be disposed of, or are required to be disposed of by the provisions of national laws" (Text of Basel Convention, 2014).

According to Basel Action Network (BAN), "E-waste includes a wide and developing range of electronic appliances ranging from large household appliances, such as refrigerators, air-conditioners, cell phones, stereo systems, and consumable electronic items to computers discarded by their users" (Puckett, Byster, Westervelt, Gutierrez, Davis, Hussain, & Dutta, 2002), (Gaidajis, Angelakoglou, & Aktsoglou, 2010).

As per European Directive 2002/96/EC, "Waste electrical and electronic equipment (WEEE), including all components, subassemblies, and consumables, which are part of the product at the time of discarding" (European Parliament, 2003, January 27), (Jain, 2008), (European Parliament, 2012, July 4).

As per European Directive 75/442/EEC, Article I(a), "Any substance or object which the holder discards or is required to discard in compliance with the national legislative provisions". Further it includes all components, subassemblies, and consumables which are part of the product at the time of discarding (Borthakur & Singh, 2012).

According to Organisation for Economic Co-operation and Development (OECD), "Any household appliance consuming electricity and reaching its life cycle end", also referred as composite waste (OECD, 2007).

These differences in definitions, of what constitutes e-waste, have the potential to create disparities in both the quantification of e-waste generation and the identification of e-waste flows across nations. The lack of a precise definition of e-waste is one of the key issues that need to be addressed on an international level (Lundgren, 2012b).

COMPONENTS OF E-WASTE

E-waste is classified as hazardous waste (Tsydenova & Bengtsson, 2011a), and it imposes many challenges on the recycling industry (Smith, Sonnenfeld, & Naguib Pellow, 2006b). Modern electronics can contain up to 60 different elements;

many are valuable, some are hazardous (Third World Network, 1991) and some are both. Several rare elements are also used (Frazzoli, Orisakwe, Dragone, & Mantovani, 2010). The types and amounts of metals used in electronics products vary with evolution of technology. The most complex mix of hazardous substances is usually present in the printed wiring boards (PWBs) that contain valuable metals like copper, silver, gold, palladium, and platinum, brominated flame retardants used in connectors, cathode ray tubes and LCD contain heavy metals like lead and barium, switches and flat screens contain mercury, older capacitors and transformers contain poly chlorinated biphenyl's (PCB's), poly vinyl chloride (PVC) coated copper cables and casing, plastics from computer hardware that release highly toxic dioxins and furans (Sum, 1991). The fraction including iron, copper, aluminum, gold, and other metals in e-waste is over 60 percent, plastics account for about 30 percent, and the hazardous pollutants comprise only about 2.70 percent of waste (Widmer, Oswald-Krapf, Sinha-Khetriwal, Schnellmann, & Bo'ni, 2005) besides alloys that mostly decreases metal's recyclability.

TOXIC ELEMENTS IN E-WASTE

E-waste contains thousands of components made of deadly chemicals, heavy metals, flame retardants, and potentially hazardous substances whose main routes of human exposure are through inhalation, dust ingestion, dermal exposure, and oral intake. Metal toxicity causes breathing difficulties, respiratory irritation, coughing, choking, pneumonitis, tremors, neuropsychiatric problems, convulsions, coma and even death (Yu, Welford, & Hills, 2006 a). Some toxic chemicals found in e-waste are analyzed below.

1. Beryllium (Be) is used as copper-beryllium alloys in computer motherboards, relays, and connectors (Taylor, Ding, Ehler, Foreman, Kaszuba, & Sauer, 2003). Beryllium refining

produces fumes, dust, and oxides which are both acutely and chronically toxic to humans. If inhaled in large concentration, it causes acute lung disease, breathing discomfort, coughing, rapid heartbeat, and death in extreme cases. Its compounds are carcinogenic in nature (IARC, 1993b) and studies have shown that people can still develop beryllium disease (beryllicosis) after many years of last exposure.

2. Cadmium (Cd) is a toxic heavy metal found naturally in very low concentration (Salomons & forstner, 1984). It is used in switches, rechargeable (Ni-Cd) batteries, stabilizers, resistors, and corrosion-resistant alloys. It is released into the environment as powdered dust during crushing and milling of plastics, CRTs, and circuit boards. It is potentially a long-term cumulative poison associated with deficits in cognition, learning, behavior, and neuromotor skills in children, causes severe pain in the joints and spine (Itai-itai disease), affects kidneys and softens bones (osteomalacia and osteoporosis) in humans. There is evidence of the role of cadmium and beryllium in carcinogenicity (Strickland, & Kensler, 1995), (Pruss-Ustun & Corvalan, 2006).
3. Hexavalent Chromium (Cr-VI) is used to protect metal housings in a computer from corrosion. It is very reactive and soluble in water, making it more mobile in environment (Mukherjee, 1998). Its corrosive nature cause skin allergies (dermatitis), damage DNA, liver, kidneys, pulmonary congestion, edema, bronchial maladies including asthmatic bronchitis, and lung cancer (IARC, 1990a).
4. Lead (Pb) as lead oxide comes from breaking of CRT, lead powder is released while removing solder from microchips, and lead fumes comes from high temperature smelting processes exposing the workers (Schutz, Olsson, Jensen, Gerhardsson, Borjesson, Mattsson, & Skerfving, 2005). In unlined

landfills, lead would dissolve in leachate or mix with ground water leading to contamination. It is neurotoxin that exerts toxic effects on the central nervous system (organic affective syndrome), peripheral nervous systems (motor neuropathy), the hemopoietic system (anemia), the genitourinary system (capable of causing damage to all parts of nephron), and the male and female reproductive systems (Harrington, Aw, & Baker, 2003). It affects mental development in children with impaired cognitive function, behavioral disturbances, attention deficits, hyperactivity, conduct problems, and lower IQ.

5. Mercury (Hg) is used as lighting device which illuminates most flat panel monitors. Workers can inhale of mercury vapour or dust which released while breaking and burning of circuit boards and switches. It affects kidneys, immune system, damage to the genitourinary system (tubular dysfunction), central and peripheral nervous systems, reduced fertility, and impairs fetus growth. When inorganic mercury spreads out in the water, it is transformed into toxic methylated mercury by microbial activity, which bio-accumulates, biomagnifies in living organisms, and concentrates through the food chain, particularly by fish (Hu, & Speizer, 2001), (WHO, 1989).
6. Brominated Flame Retardants (BFRs) like Polybrominated biphenyl (PBB), Polybrominated diphenyl ether (PBDE), and Tetrabromobisphenol-A (TBBPA) are chemically persistent organic pollutants (POP) along with toxic antimony trioxide which is used as flame retardants in electronic devices. They release carcinogenic brominated dioxins and furans as gases during fire. PBDE used in transformers and capacitors is bioaccumulative, impair brain function, and can cause liver and malfunctioning of endocrine system (thyroid damage). TBBPA used in printed circuit boards contains bro-

mine that can leach into landfills. Dust on computer cabinets contains BFRs.

7. Polyvinyl Chloride (PVC) is found in circuit boards, cabinets, and insulation on cables. It is hazardous because contains upto 56 percent chlorine which are precursors to polychlorinated di-benzo-p-dioxins and di-benzo-furans (classified as POP under Stockholm Convention) during incineration along with large quantities of hydrogen chloride gas, which when inhaled may leads to cancer, respiratory problems, affect reproductive, and immune system.
8. Polycyclic Aromatic Hydrocarbons (PAH) is generated from e-waste recycling activities and have potential impacts on soil, vegetation, and human health include breathing difficulties, respiratory irritation, coughing, choking, pneumonitis, tremors, neuropsychiatric problems, convulsions, coma and even death (Yu, Welford, & Hills, 2006 b). Epidemiological studies in the past on occupational exposure to PAH, provides sufficient evidence of the role of PAH in the induction of skin and lung cancers (Stewart & Kliehues, 2003).
9. Cobalt (Co) is extensively used in integrated circuits, semi-conductors, magnetic recording media, thin metallic films, and rechargeable batteries. It is mainly absorbed from the pulmonary and the gastrointestinal tracts and cause allergic dermatitis, rhinitis, vomiting, thyroid damage, and impaired vision. Cobalt dust may cause an asthma-like disease with symptoms ranging from cough, shortness of breath, and dyspnea to decreased pulmonary function, nodular fibrosis, permanent disability, and death.

In addition to the hazardous materials e-waste also contain a large number of valuable precious metals like Gold (Au), Silver (Ag), Platinum (Pt), and Palladium (Pd) in concentrations 40 to 50 times richer than there naturally occurring

deposits. These precious metals are extracted using hydrometallurgical processes, where valuable metals first leached into acid or alkali solutions and then they are concentrated by using various methods like precipitation, cementation, solvent extraction etc.

E- WASTE DISPOSAL AND RECYCLING PRACTICES IN INDIA

E-wastes disposal is a big problem faced by many countries including India. It is estimated that, by 2020, India could see nearly 500 percent rise in the number of old computers being dumped (Schluepa, et.al., 2009). E-waste disposal process work in two ways:

1. By removing the hazardous items;
2. By separating recyclable materials.

The three main groups of substances that may be released during recycling and material recovery, and may pose significant human and environmental health risks are:

1. Original constituents of EEE like lead and mercury;
2. Added substance during recovery processes like cyanide; and
3. Hazardous byproducts formed by incineration of e-waste like PAH.

In India, e-waste collection, transportation, segregation, dismantling, recycling, and disposal is done by unorganized small enterprise that is difficult to regulate. They employ untrained labours (more so children and women) who work in poorly-ventilated or enclosed areas without appropriate equipment and technical expertise. The process includes manual disassembly, melting, acid extraction of metals from complex mixtures, and extruding plastics.

Further incineration of printed circuit boards for desoldering and removal of chips exposes

workers to fumes of metals, particularly those in solder (often lead and tin), and other hazardous substances that can be potentially released (Tsydenova, & Bengtsson, 2011b) which pollutes the surrounding air. Inhalation and dust ingestion impose a range of potential occupational hazards including silicosis (Lepawsky, & McNabb, 2010). It exposes them to dangerous slow-poisoning chemicals on a regular basis impacting their health. Computer wastes that are land-filled produces contaminated leachate which eventually pollutes the groundwater, whereas acids and sludge obtained from melting computer chips, if disposed on the ground causes acidification of soil and irreversible damage to environment.

LEGAL FRAMEWORK IN INDIA

The environmentally sound management of used EEE imports, recycling, and their disposal has become the subject of serious discussion, debate, and significant challenge among the government, organizations, environmental groups, and component manufacturers in India. The department related Parliamentary Standing Committee on Science & Technology, under Ministry of Environment & Forests (MoEF) which is also responsible for environmental legislation, in its 192nd report on the 'Functioning of the Central Pollution Control Board (CPCB), which plays important role in drafting guidelines, has concluded that e-waste is going to be a big problem in the future due to modern life style, increase in the living standards of people, and augmentation of economic growth.

The rules and regulations for waste control in India are primarily listed under the aegis of Environmental Protection Act 1986. Despite a wide range of environmental legislation in India there are no specific laws or guidelines for electronic or computer waste (Devi, Shobha, & Kamble 2004). Electronic waste is included under List-A and List-B of Schedule-3 of the Hazardous Wastes (Management & Handling Rules), 1989, as amended in 2000 and 2003. In 2007, separate guidelines

on e-waste management were implemented, but they were voluntary and had limited impact. These guidelines include details such as e-waste composition; recycle, re-use, and recovery potential of items of economic value, identification of possible hazardous contents in e-waste, treatment, disposal options, and the environmentally sound e-waste treatment technologies (Rajya Sabha Unstarred Question No. 1887, 2009). However these rules primarily dealt with industrial waste and lack elements to deal with complex nature of e-waste.

Subsequently in 2008, these rules were amended to include toxic content and made registration mandatory for recyclers. The provision of environmental protection is delegated among various states in India. Following Supreme Court directions (Writ Petition (Civil) No. 657, 1995), the states have notified a set of hazardous waste laws and built a number of hazardous waste disposal facilities in the last ten years. However, the Controller and Auditor General (CAG) report found that over 75 percent of state bodies were not implementing these laws (Writ Petition (Civil) No. 10, 1995), giving rise to sloppy enforcement of e-waste related legislation.

India is also a signatory to the Basal Convention (under UNEP) on the control of Transboundary Movement of hazardous wastes and their disposal but officially opposes enforcement of BAN Amendment (Basel Action Network, 2011). The regulations banning the importation of hazardous waste for disposal are weak and an imported consignment of electronic scrap still comes into the country, as they are not properly classified as plastic scrap or mixed waste. In 2014, India generated 17 lakh tonnes of e-waste increasing growing at rate of 4-5 percent per year. With such exponential growth, the Indian government finally woke up and responded by framing the E-waste (Management and Handling Rules), 2016 with the aim to make re-cycling of e-wastes environmentally friendly. To begin with, the rules put India along with a select club of nations like the United States and many European nations to have legislation to regulate and manage e-waste. These rules recognized the producer's liability

for recycling and reducing e-waste in the country. It will apply to every producer, consumer, and bulk consumer involved in manufacture, sale, purchase, and processing of electronic equipment or components. It also brought disposal of CFL lights under its preview.

While the rules seem impressive on paper, environmentalist argues that there is total oversight of the ground situation. These rules ignore the unorganized sectors where 90 percent of the e-waste is generated. Also there is lack of a safe e-waste recycling infrastructure in the organized sector where only a fraction of the e-waste (estimated 10 percent) finds its way to recyclers due to absence of an efficient take back scheme for consumers. The ministry is giving the producers of EEE a breathing period of one year to set up their collection centers (Kumar & Shah, 2014) and develop technical guidelines for the environmentally sound management of e-wastes. Thus computer, mobile handset, and consumer goods manufacturers, will be required to come up with e-waste collection centers or introduce 'take back' systems. Therefore over reliance on the capacities of the informal sector poses severe risks to the environment and human health.

STRATEGIC INTERVENTION

A smart e-waste management system have to access current e-waste situation, recognize that e-wastes is complex mixture of hazardous substances, reduce the generation of e-waste through smart manufacturing and maintenance, reuse till functioning of EEE, and finally recycle those components that cannot be repaired or refurbished. Recycling and reuse of materials are the next level of potential options to reduce e-waste (Ramachandra & Saira, 2004). Based on current situational analysis in India, following strategic intervention is proposed:

1. Extended Producers Responsibility be introduced that involves collection and disposal of e-waste in environmentally sound manner

- or else stringent financial penalties must be imposed by state governments.
2. Update the legal and institutional framework for e-waste management including effective enforcement of laws, regulations, and standards. Introduce strict liability clause in proposed rules for effectiveness.
 3. Defining responsibilities of prime stakeholders at the level of government, supply chain, consumers, and develop a comprehensive policy that address all issues ranging from production, trade to final disposal, including technology transfers for the recycling of electronic waste.
 4. Raise public awareness, advocate for e-waste management across all stakeholders through public-private-partnerships linkages.
 5. Introduce a concept of 'e-waste exchange' as an independent market instrument offering services for sale and purchase of e-waste.
 6. Tighten import norms and custom procedure at port of entry. Maintain statistical records of imported of EEE goods for further analysis including their final disposal.
 7. Create a facilitative environment for investment in e-waste handling and disposal infrastructure by creating modern e-waste recycling facility and provide tax incentives to make it more effective.
 8. Introduce advance recycling fees. Also setup and operationalise an e-waste fund to benefit those working within this industry.

FUTURE RESEARCH DIRECTIONS

Developing national approach to handle e-waste, strengthening regulatory environment, designing new methods to increase waste collection, integrated modelling concepts to build waste recycling capacities, and building awareness among people can be carried out on larger scale across India. Also study of impact on toxic heavy metals individually as well as their cumulative effect on ecosystem needs to be further explored. Further quantities of waste material that moves between countries,

waste flows within a country and between countries and hazardous substance emissions associated with manual recycling process, social, and its health impact on children and women can also be further investigated. A comparative study of various EEE product categories can made.

CONCLUSION

From the discussion above, it is aptly clear that India faces an enormous task of handling and disposing growing piles of e-waste and its impact on human health (more so of women and children) and natural environment has increased manifold. Therefore policy level interventions should include strong e-waste regulation, tight control on import and export of e-wastes, and facilitation in development of recycling infrastructure. Lack of strict enforcement of legislation is also worrisome situation.

It requires building of public awareness, establishment of institutional infrastructures (including e-waste collection, transportation, treatment, storage, recovery, and disposal) at national and regional levels. Furthermore product end-of-life management should be made a priority during design of new electronic products using green materials, innovation in product technology, life cycle analysis, public outreach, and so on. Beyond conservation of raw materials and energy, there are additional environmental benefits of recycling, such as reduced land disturbance, water use, air emissions, and waste generation which in turn improves efficiency and environment. In conclusion it is time for us to look deep and ahead today as tomorrow it will be too late to act.

KEY TERMS AND DEFINITIONS

Dioxins and Furan: These are persistent environmental pollutants (POPs), formed as unintentional by-product during e-waste incineration to recover valuable metals.

Electronic Waste (E-Waste): It refers to EEE waste, including all components, subassemblies, and consumables which are part of the product destined for reuse, resale, salvage, recycling or disposal at the time of discarding.

Environmental Hazard: A substance, state or event which has the potential to threaten the surrounding natural environment that adversely affects people's health (Pollution and Natural disasters).

Environmental Sustainability: It is defined as could be defined as a condition of balance, resilience, and interconnectedness that allows human society to satisfy its needs while neither exceeding the capacity of its supporting ecosystems to continue to regenerate the services necessary to meet those needs nor by our actions diminishing biological diversity.

Metal Poisoning: Toxic metals in certain form and dose sometimes imitate the action of an essential element in the body; interfere with the metabolic processes that cause illness (metal poisoning).

Occupational Hazard: It is risk accepted as a consequence of a particular occupation and they encompass chemical, biological, psychosocial, and physical hazards.

Recycling: It is the process of converting waste materials into reusable objects; dismantling, separating fractions, and recovering material in order to reduce the consumption of fresh raw materials, energy usage, air pollution (from incineration) and water pollution (from land filling) from e-waste after the lifespan of the equipment.

Green IT and the Struggle for a Widespread Adoption

E**Edward T. Chen***University of Massachusetts – Lowell, USA*

INTRODUCTION

Since the inception of computers, both for business and personal purposes, there have been multiple environmental issues that resulted from this technology. The complex electronics require significant electricity to operate them, large amounts of energy to keep them cool for prolonged usage, and various chemicals and resources to construct them. Notably, within the last decade, there has been a movement building for the ecologically responsible construction, use and disposal of computer systems and their components, including monitors, batteries and printer cartridges. This initiative is commonly known as Green Information Technology (IT), or Green IT.

As both consumable and enterprise level computing products grows, a need for sustainability arises. A balance between the energy consumption and the provided services is required to ensure the environment can survive the influx of billions and billions of devices. Concepts like the Internet of Things, Big Data, smart devices and phones, and complex business analytics for corporations all drive the need for more connected devices. These devices consume more electricity than ever before and data runs the planet (Murugesan & Gangadharan, 2012; Subburaj, Kulkarni, & Jia, 2014).

The Green IT (green information technology) is the practice of environmentally sustainable computing (McLaughlin, 2013). The lack of regulations, standardizations, and standard operating procedures has left this notion out of the mainstream and under the radar of many organizations' information technology (IT) implementations. Several ideas at different levels have

been proposed over the years. Its current adoption rate is not enough for sustainability. G-Readiness framework combines properties, processes, and components that are well defined and measurable to ensure success in the greening of IT (Molla, Cooper, Corbitt, Deng, Peszynski, Pittayachawan, & Teoh, 2008). Large technology companies have designed, patented, and implemented as a way to offer a differentiated service and a competitive advantage through green IT. Some of their innovations have the potential to be replicated for further successes (Murugesan & Gangadharan, 2012).

BACKGROUND

Though there is not a general consensus on the exact definition of Green IT (also referred to as green computing, green information and communication technologies (ICT), or ICT sustainability), the most commonly accepted definition was coined by San Murugesan, an outspoken university professor, in his 2008 article entitled "Harnessing Green IT: Principles and Practices". Murugesan defined green IT as "the study and practice of designing, manufacturing, using and disposing of computers, servers, and associated subsystems... efficiently and effectively with minimal or no impact on the environment" (Murugesan, 2008). Multiple efforts can be made, both from individual home users as well as those of entire businesses, to reduce the negative impact on the environment from the technology they are using.

The hardware, software, and components that make up technology are always changing and evolving. Some components like computer

processors, are gaining the ability to process information faster while the integrated circuits are getting smaller. Other devices gain new features with each new release and make the older model seem outdated or no longer usable. This perception is particularly accurate with personal technology such as laptops, phones, and tablets. Unused excess hardware accumulates in staggering quantities. In the corporate world, technology is advancing faster than the needs of many businesses. Data centers are filled with high-powered servers and storage devices, which run 24/7/365 in a production environment. Attractive and enticing price points combined with clever marketing presentations convince companies that the deployment of these systems is necessary to solve their IT and IS (information systems) problems (Nguyen, Cheriet, Lemay, Reijs, Mackarel, & Pastrama, 2012).

According to Gartner Research, there are 2 billion computers in use today. They predict that the number of devices and things, items such as thermostats, refrigerators, cars, and other non-traditional computing hardware and sensors, on the Internet could surpass 40 billion by the year 2020 (Akhgar, Pattinson, & Dastbaz, 2015). Greenpeace estimates that if the Internet were a country, it would fall between Japan and Russia, or 5th place, in overall electricity consumption in the world (Cook & Pomerantz, 2015). 50% of the world's population owns a cellular telephone. This number is only going to go up as emerging countries begin to rely on the same technology as First World countries. Tablets are expected to outpace computers in sales and use before the end of this year (Akhgar, Pattinson, & Dastbaz, 2015). The amount of technology in use and the amount of technology that has been cast aside present two challenges for the concept of green IT: reducing energy consumptions of current hardware and finding ways to safely recycle previous hardware that is no longer in use. Stated in a different way, it is solving the two problems of how to reduce CO₂ emissions and how to lower e-waste (Ahmad & Ranka, 2016; Elliot, 2007).

A study was conducted in 2009 to investigate why the lack of growth with implementing and supporting green IT initiatives and standards. It surveyed Chief Information Officers (CIOs) and other IS professionals to find the "barriers" that keep green IT from being implemented. The results of the survey show no surprises, citing a lack of business leadership; the unknown costs versus cost savings for green IT solutions, and the absence of value by turning to green alternatives (Dedrick, 2010). Also uncovered through the same survey was the importance of government incentives or regulations mandating converting to green IT. Without formal direction or instructions to do so, companies are not eager to start the perceived arduous process to switch.

INFORMATION TECHNOLOGY'S GREEN PROBLEM

Energy consumption is a major aspect of IT, with the methods to produce electricity still largely powered by the depletion of fossil fuels such as coal and oil. It is estimated that the carbon dioxide (CO₂) produced by a single desktop computer over its lifetime is 1,096 kilograms (Thomson & van Belle, 2015). This consumption and pollution is amplified by the increasing occurrence of non-efficient software and coding, requiring computers to take longer periods to process finite tasks. A 2009 disputed study found that the average search using the popular search engine Google produced approximately 7 grams of CO₂ and required roughly half of the amount of energy needed to boil a kettle of water (Swaine, 2009; Warman, 2009). A portion of the total electricity consumed by IT is to power the computers and their components, while an even larger portion (30%) is used to cool the computers and their related hardware, particularly in the data centers associated with these information systems (IS) that house the computers and their related components, such as servers and power supplies (Murugesan, 2008; Nguyen, 2012).

The majority of businesses routinely require that their data centers remain cooled at all times at temperatures less than 70 degrees Fahrenheit (21 degrees Celsius) and one study found that only 7% of data centers in the world run at or above a temperature of 75 degrees Fahrenheit (23.8 degrees Celsius) (Mitchell, 2013). The majority of energy spent to cool these facilities utilizes air cooling as opposed to other more efficient methods of cooling and require continuous operation to maintain the set temperature, regardless of whether the IT is even in use. It is estimated that many processors sit idle between 85 to 95% of the day, requiring nearly the same amount of electricity as when active (Shah, 2012). Energy consumption utilized by IT is continually increasing as IT becomes more prevalent in society, with electricity usage by data centers in the United States rising 74% between 2000 and 2010 (van Bussel, Smitter, & Vandepas, 2015).

Computer production requires extensive resources and chemicals, with their associated production facilities consuming large amounts of energy for daily operations as well as climate control. Materials such as lead, mercury, cadmium and hexavalent chromium, combined with large amounts of water, aluminum and plastic, are required to make these machines and their intricate components. With today's pressing need for IT, this technology is more necessary than ever before to ensure each company and household remains capable of performing all manners of tasks and communications both within their community and throughout the world. Despite these high production levels of state-of-the-art equipment, many networks built to last 33 years are seeing themselves disposed of after only 3 to 5 years of use, mainly due to a knee-jerk reaction by their owners to consistently replace and update their 'obsolete' systems for the supposedly required next generations of technology (Ahmad & Ranka, 2016; Ogden, 2013).

These discarded systems are then largely disposed of inappropriately due to minimal disposal regulations and recycling options for IT, resulting

in approximately 80% of the systems being dumped in nearby landfills or exported to developing countries such as China and Pakistan where the disposal regulations are less stringent. In 2008, it was estimated that two-thirds of the estimated 870 million personal computers that will be made within the next five years will end up discarded in landfills (Murugesan, 2008). In 2006, the global production of IT-related waste was estimated at 20 to 50 million tons per year (van Bussel et al., 2015). These inefficient practices regarding IT are contributing towards global warming, the expedited depletion of natural resources, and increasing the waste in landfills, leading to the pollution of both the land as well as water sources in the vicinity.

SOLUTIONS AND RECOMMENDATIONS

Despite this dire situation, many options exist to implement green IT and make computing less of a hazard on the environment. The first practice the majority of companies and households can perform is power management, ranging from simply turning off their computers when not in use to providing a power management features to the IT to automatically reduce its electrical load following a period of inactivity. This feature, known as sleep mode, can reduce costs by 60 to 70% and now comes standard on most new computer systems after lengthy pressure was exerted on the manufacturing industry to standardize power-saving features in their products (Murugesan, 2008). Another prevalent shift in the IT industry is the development of ecological hardware that requires much lower levels of electricity to operate as well as attempts to increase the lifespan of the equipment. An example of this innovative new technology is the Atom series of energy-efficient processors designed by Intel. They are ultra-thin and lightweight and their use in IT reduces the space and energy required on the IS. In addition, the fit-PC by Compulab is a series of fanless per-

sonal computers that are smaller and require less power than traditional IT, often able to function for long periods of time on batteries and requiring lower-power processors such as the Intel Atom.

Monitors that display the IT images have improved significantly in technology and availability, greatly reducing energy costs. Light-emitting diode (LED) displays are now very comparable in cost and beneficial due to their use of significantly less electricity than liquid crystal display (LCD) monitors as well as their predecessor, the cathode ray tube (CRT) display. In 2014, the German ion research company GSI Helmholtz had created the world's most energy-efficient supercomputer, the L-CSC, in Frankfurt as evidenced by the 'Green 500' report released in November of 2014. Despite being incredibly energy-efficient, the computer was also rated the fourth fastest computer in Germany upon its release (Phys.org, 2014), demonstrating that green computers can be just as powerful and effective as standard models. In addition, efficient coding of software and other applications can significantly reduce the time required for computing processes by increasing the software processing speed on each computer, reducing the electricity consumption as well as energy required to cool the IS. The increasing development and availability of green IT hardware and software are helping provide efficient alternatives to traditional IT equipment used throughout the past 30 years.

There is a wide variety of cooling system methods that can be used to maintain a requisite temperature in the spaces that house computer systems. In addition to traditional air conditioning, alternative methods such as air-side economizers for facilities and liquid cooling systems for PC's are showing themselves to be viable options for keeping equipment cool and, in many cases, requiring a fraction of the cost of air conditioning while being several hundred times more efficient. Despite these benefits, it is understood that a massive overhaul of a company's cooling systems, as well as the required investment that would accompany it, are not simple fixes that can be implemented

overnight. Despite these hurdles, the primary solution to high cooling costs that is immediate and is being recommended by leading green companies (such as FedEx, Raytheon and Northrop Grumman) as well as the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) is to simply raise the temperature in data centers. Rather than require a temperature of no warmer than 70 degrees Fahrenheit (F), multiple experts state that all companies should be safely able to raise the temperature of its data centers to 75 degrees F and possibly even as high as 80.6 degrees F to maintain the climate required to protect the IS while simultaneously reducing the energy demands of the facility cooling systems (Mitchell, 2013).

Finally, the most effective solution to reducing energy, hardware, and software costs for all entities utilizing IT seems to be virtualizing equipment. Virtualization is the practice of consolidating servers, desktops, and any other types of equipment to fewer pieces of equipment that can still handle the load requirements. Server virtualization is common in which many virtual servers are hosted on a smaller number of more powerful servers. Instead of having 20 servers throughout the country, entities can invest in three larger server facilities that can still provide full network coverage throughout the company while significantly reducing facility operating, cooling and maintenance costs (Pandi & Somasundaram, 2016). Northrop Grumman is an example of this type of virtualization, eliminating 4,000 physical servers and combining 19 data centers and 81 smaller server rooms into only three facilities (Mitchell, 2013).

Desktop virtualization works in many ways by the same principles. Thin clients are stateless and fan-less computer desktop terminals with no hard drives. They simply link in to the data center to access all desktop capabilities while only drawing one-fifth of the electricity of a traditional desktop computer (Murugesan, 2008; Nguyen, 2012). Even virtual chillers are becoming a frequently-utilized concept, providing climate controls to multiple

facilities within the area at a fraction of the cost each facility would require to cool through individual systems. These concentrated efforts may take considerable planning and expense to arrange in the majority of circumstances, but the initiatives pay off for years in the future with exponentially lower energy and facilities costs to the companies (Pandi & Somasundaram, 2016).

LIMITATIONS

Despite the obvious benefits and wide array of alternatives for green IT that are available to companies now more than ever before, the main deterrent is that there are very minimal laws of compliance and regulation regarding green IT. Instead of strict legislation requiring specific changes to be implemented, the majority of initiatives and alternative options available within the United States and beyond are solely advisory. The United States Environmental Protection Agency (EPA) founded the Energy Star program in 1992, giving it a significant upgrade in 2006 to include computers and other IT, but it is still mainly an optional program and not a requirement for all appliances and equipment to have the green star logo depicting environment-conscious operation. As of 2008, only 26 of the 50 United States had established a statewide recycling program for the proper disposal of older computers. The Green Electronics Council created the Electronic Product Environmental Assessment Tool (EPEAT) as a method to assist prospective IT buyers through the ranking of available for purchase equipment by more than 50 criteria topics, assigning scores based on how green the technology is (Ahmad & Ranka, 2016).

In 2007, President George W. Bush signed Executive Order number 13423, which required all federal agencies to utilize EPEAT when purchasing new computer systems and requiring all vendors contracted by the Federal government to utilize EPEAT in their system purchases. President Obama recently modified this requirement in March of 2015 with Executive Order 13693, stating

that all government procurements of electronics should “meet or exceed specifications, standards, or labels recommended by (the) EPA” (Moodie, 2015). This legislation is expected to reduce the prominence of the EPEAT ratings system by instead requiring companies wishing to do business with the federal government to follow one of the many recommended ratings systems, rather than specifically the most well-known, EPEAT, but at least the directive to procure green equipment remains a priority.

The Restriction of Hazardous Substances (ROHS) in Electrical and Electronic Equipment Directive makes significant restrictions on the European Union market for equipment containing specific amounts of certain hazardous substances (Murugesan, 2008). Since August of 2006, Greenpeace International has produced their quarterly Guide to Greener Electronics, ranking several companies on their overall use (or lack thereof) of green IT. Then in 2007, several manufacturers of computer equipment (including Dell, HP, Microsoft, and Intel) formed the Green Grid, a consortium dedicated to making data centers and information systems more ecologically efficient.

Four general drivers for a company to choose to utilize green IT are economic, regulatory, market opportunity, and finally influence from social, cultural and political pressures (Thomson & van Belle, 2015). Despite the wide variety of laws and regulations aimed to transform companies into becoming more environmentally-conscious, the majority remain overwhelmingly optional for companies to follow. Thus, the primary motivator for companies to go green is economic, strongly appealing primarily to their own self-interests (Bohas & Poussing, 2016). Implementing green methods reduces energy costs. Green practices can extend the life of the IT and decreases the costs of disposal of obsolete equipment. In addition, following green practices will set a positive example for other companies to follow and can greatly increase the public image and reputation of the firm, known as “Green corporate image” (Bohas & Poussing, 2016).

However, many businesses look at green IT through a purely economic mindset. Despite the benefits to the business and the environment, fiscal incentives or government subsidies will have to be involved to aid the businesses in the costly transition towards greener IT (Mitchell, 2013). Through the use of several of the advisory organizations listed above, there is a growing voice for green practices with increasing pressures being placed on both the companies as well as the governments of the world to enact stricter regulations to enable change. There is also a small but growing market opportunity for companies that specialize in green IT consulting to help companies shift to cost effective and ecological green practices. This will likely help increase the prevalence of green computing in the years to come.

Another major benefit of green IT is that for the majority of the process, managerial practices should not have to change significantly in the business settings. The process of shifting systems to greener alternatives will require close coordination and decision-making between the management of each business and the IS personnel involved. Following these shifts, the systems will largely function in a way that does not change the day-to-day aspects of each normal business process. The employees will likely just see a greater emphasis on turning off their computers at the end of the day and other similar green initiatives that are both understandable and significant practices that businesses can implement to help their environment.

Other than the higher costs that are still regularly associated with newer technology, it does not appear to be any subsequent technological problems or complications that will arise as a result of green IT. Alternatively, green methods are designed and implemented specifically to reduce the existing energy problems that have been prevalent for decades. They are consistently being seen as reliable solutions to the disadvantages of outdated technology.

FUTURE RESEARCH DIRECTIONS

The Internet of Things (IoT) promises a lot of innovation through sensors operating and interoperating together. It has already solved problems that previously having no operational solutions. IoT brings with it immense computing capabilities and endless possibilities that combine science fiction with an improved quality of life. The need for a seeming endless amount of storage to keep the big data collected from over 40 billion IoT devices. This alone facilitates the immediate need for green IT. However, this technology and this level of capability can also drive green IT initiatives.

As Big Data becomes a term that continues to grow in usage, the amount of data is also growing. The more data that needs to be stored, the more natural resources it will take to power the servers, keep them cool, and house them in large facilities. One innovative team decided to see if solving green IT can be accomplished by reducing the abundant amount of data that is currently burning up more energy than necessary. While this study still needs further development, it helps to further the cause here of helping to define how to make green IT more accessible to the general IT public. It categorizes green IT into six core components. The first component is longevity of the hardware. How well was the product produced? What is the expected life span? The second component is software optimization, allowing for the hardware to consume less resource to compile and run the software. Third one is power management in finding the right formula and standard to shut off computer resources when not in use. The fourth component is the recycling of materials and not just recycling computers but finding alternative uses for the hardware. Fifth component on the list is telecommuting. An indirect benefit from fewer cars on the road will reduce carbon dioxide emissions. And finally, the sixth component is energy-efficient computing or low-power IT (van Bussel, Smitter, & van de Pas, 2015).

Current and previous research has been focused mainly on trying to better understand how green IT can be codified for implementation. Longitudinal studies have looked at ways that Green IT could be standardized, means to quantify form over function, and even look at the individuals who will need to support it and their impressions from a psychological approach. If green IT is to surpass its current adoption rate, stronger research needs to be conducted by pairing technology with green philosophies. For example, implementing power-saving functionality at the firmware level of a network switch can save energy for the entire network. Sensors abound from the Internet of Things revolution should make collected data meaningful for experiments and publish new findings and standards easier to reach target audiences (Kaushik & Vidyarthi, 2016).

CONCLUSION

Through a series of missteps or misinterpretations, green IT is still struggling to find its place within the technology field. Studies have been conducted; outcomes have been published; and successes have been documented; but something remains missing in this vital area that blends innovations with ecological awareness and respect. The G-readiness framework is probably the most concrete way for a common business to assess the potential of green IT for them based on the factors most important to keeping the business operational. And while the framework might seem daunting at first, there is a structure to it that forces a common sense and logical approach to reduce energy and look at IT in a smarter way.

Companies have adopted the virtualization of servers. Virtualization is not considered a win for green IT, nor did it help to mainstream the concept. Instead, IT professionals everywhere have no idea that when they learn how to run multiple services virtually, they reduce their carbon footprints. Those same IT professionals will be needed to collaborate with their business

counterparts to ensure they can provide innovative solutions to problems as they arise. This will be the cornerstone to the implementation of green IT within a business.

The green IT community is still small and many of the same people have been working together on the different studies and experiments trying to garner a stronger and larger following. Social media should be exploited to ensure the next generation of IT professionals and operators know how to think green right from the beginning. It's the Millennials that will be faced with the green IT challenge, a challenge to sustain a healthy planet through the Internet of Things and the 50 billion devices and zettabytes worth of data that comes with it. Green IT must become the new normal before that time. It is no longer an option, and it is no longer something for someone else to worry about.

Currently, there are not enough green IT regulations implemented through the governments of the world, including that of the United States. They would require at least a small percentage of its implementation by the business sector to kick start the unanimous shift towards fully green computing. Further, until commercial entities are required to comply with green IT practices, the personal-use market will also not attain compliance and yet another decade could likely pass resulting in very minimal improvements. Until the requirements are enacted, the majority of businesses will simply not switch over. Before they are able to devote the requisite time and energy to make this essential shift, they want to see that green IT practices can benefit them significantly.

The concept of Green IT is steadily increasing in prominence and the benefits such as reduced energy costs are making green IT practices very attractive to all businesses. They desire a sense of longevity and a cost-effective IS infrastructure. The omnipresence and convenience of IT in all venues of life factored in with the environmental benefits from computing. The reduced greenhouse gas emissions evidenced from telecommuting, online education enterprises and video telecon-

ferencing, will keep the IT industry strong and a permanent fixture in today's society. Green IT will eventually become the standard to follow, but the implementation will be much slower if major elements do not become mandatory through the use of effective legislation and increasing numbers of entities willing to set the correct industry examples.

KEY TERMS AND DEFINITIONS

Carbon Footprint: The total amount of greenhouse gas emissions usually expressed in tons of carbon dioxide (CO₂).

Data Center: A physical or virtual infrastructure used to house a large group of networked computer servers for the remote storage, processing, or distribution of large amounts of data.

Energy Consumption: Amount of energy consumed in a process or system, or by an individual, organization or country.

e-Waste: Any old, end-of-life or discarded electronic or electrical devices or their components.

Green IT: Green information technology is the practice of environmentally sustainable and responsible use of computers and related resources.

Identification of Green Procurement Drivers and Their Interrelationship Using Fuzzy TISM and MICMAC Analysis

Surajit Bag

Tega Industries South Africa Pty Ltd., South Africa

INTRODUCTION

Green procurement is sourcing products and services that cause minimal adverse environmental impacts. It incorporates human health, social and environmental concerns into the search for high quality products and services at competitive prices. Green procurement is generally considered a mammoth task by the procurement managers. Recently focus has been given by regulatory bodies to apply pressure on firms for implementing green programs. Environment protection bodies are regularly organizing seminars and conferences to educate and train managers in such greening initiatives. In some countries the government has developed green specifications for items and mandatory part of tender requirement for public procurement. However, the green procurement programs are still under nascent phase in most developing countries.

The present research is motivated based on the study of Azevedo et al., (2011) where they have pointed potential future research area in exploring the enablers and barriers influencing companies in taking green procurement decisions. Secondly, Appolloni et al., (2014) conducted a review on green procurement considering the time frame between 1996 and 2013 but does not highlight the inter-relationships between the drivers of green procurement practices and they have also kept it under one of future research directions. They have also mentioned the need for strong qualitative and quantitative research to support the progress of green procurement.

The objective of the current study is to identify the leading drivers that influence green procurement programs and determine the interactions among the identified drivers. This chapter is structured into four additional sections. The next section presents the background of the study which helps to identify the green procurement drivers. The third section introduces Fuzzy TISM. Finally, conclusions, limitations and directions of future research are presented.

BACKGROUND

In this section an attempt has been taken to briefly explain the key drivers of green procurement.

Government Policy and Regulations

Governments are among the largest consumers in an economy. The public sector on average spends 45%-65% of their budgets on procurement. Given this substantial purchasing power, governments have enormous leverage to stimulate and drive markets for sustainable production and consumption when they make a determined effort to purchase 'green' products and services. Adopting such an approach is a smart form of procuring goods and service – it not only improves the efficiency of public procurement but also uses the public market power to bring about significant environmental and socioeconomic benefits. Supply chain management operates within a regulatory framework set by National Government and

extended by provinces and local governments to specific policies, legislation and regulations. In South Africa for instance important legislation influencing this function includes the Public Finance Management Act (1999), Preferential Procurement Policy Framework Act (2000), Preferential Procurement Framework Regulations (2001) and National Treasury Regulations (2005). The Municipal Finance Management Act (MFMA) of 2003 governs the financial and supply chain management functions of Local Government. In developing green procurement policies, local government would need to ensure that these policies: are aligned with their existing Supply chain management regulatory frameworks; avoid a clash between the Preferential Procurement regulations and environmental principles or criteria in the policy; incorporate green procurement in all dimensions of the supply chain management cycle; and institutionalize green procurement within the existing structures set out by the regulatory framework. Government policy and regulations positively influences green procurement (Min & Galle 1997; Diabat & Govindan 2011; Hassini et al., 2012; Bag., 2014; Appolloni et al., 2014)

Total Quality Environmental Management

Firms with successful TQEM programs will have more formal mechanisms for interacting with suppliers. Business units with successful TQEM programs exhibit a greater degree of competitive focus and strategic sourcing. In every step of the manufacturing process there will be quality check to avoid rejections and wastage and this will assist in saving natural resources. TQEM positively influences green procurement (Khidir et al., 2010; Diabat & Govindan 2011; Ageron et al., 2012; Dubey et al., 2013; Bag., 2014; Bag & Anand., 2014; Dubey et al., 2014).

Management Support

Management support is important in success of any projects and specially for green procurement

programs where strategic decisions are mainly involved. Management support have positively influenced green procurement (Min & Galle 1997; Zhu et al., 2008; Arslan 2010; Bag., 2014).

Management Review

Management review periodically is necessary to check the progress of green procurement programs and see that timelines are met. The review will capture the bottlenecks, critical paths and develop strategies to find out ways to complete the activities at economical cost within the timeline. As per expert opinion management review positively influence green procurement.

Continuous Education of Employees

Organizations practicing green procurement must have the transformation and diversity manager to carry out the necessary trainings of employees. Training will assist employees in gaining knowledge and deeper understanding of green procurement and its importance in supply chain management. Moreover, the training budget must be utilized carefully in proper training and must be aligned with the company mission and vision so that organization ultimately benefits in the long run. As per expert opinion continuous education of employees positively influences green procurement.

Cross Functional Team Building

In a manufacturing firm there are people from planning, procurement, production, quality assurance, logistics and other functions. Since green procurement involves close coordination with all related supply chain functions therefore it is imperative that organization form a green procurement committee comprising people from all functions, i.e. a cross-functional team to drive the green procurement project. This committee will be responsible for generating weekly progress reports, communicating to internal and external environment, maintain records of consumption

of resources, reduction in energy usage and associated cost savings. As per expert opinion cross functional team building positively influences green procurement.

Organization Culture

Empowering junior managers and creating innovation culture among employees will facilitate green procurement practices. Ultimately the organisational culture, structure and process must support the green procurement practices. As per expert opinion organizational culture positively influences green procurement.

Green Process and Technology

Introducing 'green' tendering criteria can influence the marketplace and result in new entrants in the field of environmental technologies and products - potentially resulting in increased competition and reduced prices. Firms must remove the obsolete machinery and convert to green process and technology (renewable source of energy, reducing utility costs, environmental innovation and source reduction) to drive the green procurement programs. Green process and technology positively influences green procurement (Green et al., 2000; Hassini et al., 2012; Bag., 2014).

Information System Infrastructure

IT Eco-Efficiency and IT Eco-Innovation is important dimension of information system infrastructure required to drive organization wide green programs. Additionally, SAP, ERP, RFID, and data analytics are important tools to derive the MIS reports for assessing the progress of green procurement projects. IT infrastructure positively influence green procurement (Green et al., 1998; Hervani et al., 2005; Bag 2014).

Green Design

Driving the green procurement project starts in the design stage to ensure that products comply

with restrictions on specified chemical substances in parts and materials, while complying with obligations for labeling, information provision and energy-saving standards for finished products. The green design should comply with environmental norms and regulations such as WEEE, RoHS, REACH, EU Directive on Packaging and Packaging Waste. Green Design positively influence green procurement (Mavi et al., 2013).

Re-Use, Re-Engineering, and Recycling of Products and Materials

The 3 Rs' forms the basis of any green procurement programs and enhance cost savings and savings of natural resources. 3Rs' positively influence green procurement (Mavi et al., 2013).

Supplier Flexibility

It is critical for suppliers to adopt flexibility and supply alternate material as per revised bill of material in green procurement projects. The supply risk must be minimized by supplying the alternate material in time at economical costs. Supplier flexibility positively influence green procurement (Mavi et al., 2013; Bag, 2016b)

Suppliers' Capability to Innovate

It is imperative that supplier has the capability of innovation by demonstrating knowledge and willingness by coming with new eco-products at cheaper costs. It positively influences green procurement (Min & Galle., 2001; Chiou et al., 2011; Ageron et al., 2012).

Supply Risk Management

Green procurement adopt some of the best practices which automatically minimizes the supply risks associated with traditional supply chain management. It positively influences green procurement (Ageron et al., 2012; Bag 2014; Bag & Anand., 2014; Dubey et al., 2014).

Trust Building in Suppliers

Trust is a soft factor associated with green procurement. It positively influences green procurement (Ageron et al., 2012; Ji et al., 2014).

Low Supplier Lead Time

Green procurement prerequisites best operational practices such as vendor managed inventory, just in time approach and lean manufacturing to optimize costs. Automatically the supplier lead time becomes low in such cases and suppliers are able to deliver material as per delivery schedule. This involves proper strategy building and careful monitoring. Therefore, supplier lead time influences green procurement (Ageron et al., 2012; Bag, 2014; Bag & Anand., 2014; Dubey et al., 2014).

Customer Satisfaction

Customer satisfaction is the outcome of good green procurement practices and measured as a success parameter in any green programs. It positively influences green procurement (Diabat & Govindan, 2011; Ageron et al., 2012; Bag., 2014; Bag & Anand., 2014; Dubey et al., 2014).

Annual Savings From Green Procurement Practices

Organizations derive both tangible and intangible benefits from green procurement practices. The direct savings from green procurement practices are significant and highly motivates the procurement managers. As per expert opinion annual savings from green purchasing positively influences green procurement.

Annual Saving of Natural Resources

The annual savings of natural resources motivates managers in driving green procurement projects. The key areas where reduction can be achieved are: consumption of coal used to fire boiler, diesel oil in forklifts, steam for running hydraulic

systems and compressor, energy for utility and paper for printing will lead to significant savings of natural resources. As per expert opinion savings of natural resources positively influences green procurement.

Procurement Excellence

Adopting best world class sustainability practices such as green procurement leads to procurement excellence. Therefore, procurement excellence is the outcome and considered as a variable for measuring success of green procurement (Bag, 2016a).

DATA ANALYSIS

The current study intends to develop green procurement theory based on fuzzy total interpretive structural modeling (Fuzzy TISM) approach. Fuzzy TISM is an advanced method and designed in a manner to capture both the statements of respondents as well as logic and interpretation. TISM has greater explanatory power than other established inductive approaches.

Fuzzy Total Interpretive Structural Modeling (FUZZY TISM)

The steps of Fuzzy TISM have been followed as per Khatwani et al., (2015). The data analysis is segregated into following sub-sections:

Start the Decision Making Process

In the current study, the responses of five experts from manufacturing sector have been gathered. The input has been utilized to refine the drivers and further used in modeling.

Selection of Criteria and Sub Criteria of Green Procurement

This is the second step in Fuzzy TISM modeling approach. For the purpose of this study, twenty-

five drivers were identified from literature which influences green procurement practices and finally refined through experts' opinion. The final twenty sub criteria are presented in the previous section.

In the next step the process of gathering responses for fuzzy TISM has been explained in details.

Gathering Responses and Calculation of Aggregated SSIM

For the purpose of study, the responses of five procurement managers from manufacturing sector has been collected for evaluation of interrelationship among selected drivers. These experts are well experienced with the green procurement practices. A joint meeting was organized with these five experts and the research problem and methodology was presented and explained to them in 30 minutes' duration. Further they were requested to fill up the VAXO matrix. The entire process of filling up the VAXO matrix separately by these five experts took almost one hour. From the submitted five separate VAXO matrices, finally the aggregated SSIM matrix was calculated by applying mode. The aggregated SSIM matrix is shown in Table 1 (Appendix).

Calculation of Fuzzy Reachability Matrix

The fuzzy reachability matrix is generated from aggregated fuzzy SSIM matrix which was presented in the above stage. The fuzzy reachability matrix is shown in Table 2 (Appendix).

Calculation of Final Fuzzy Reachability Matrix

The final fuzzy reachability matrix is derived from step above and presented in Table 3 (Appendix). From the final fuzzy reachability matrix, the dependence power (X) and driving power (Y) is calculated based on summing of columns and rows and calculating the crisp value. The crisp value of each element is used as an input to develop fuzzy MICMAC analysis.

Driving Power and Dependence Power Matrix (MICMAC) Based on Fuzzy Reachability Matrix From Table 3

See Figure 1.

Figure 1. MICMAC analysis based on crisp values

Discussions Based on MICMAC Analysis Based on Fuzzy Reachability Matrix

Cluster 1 - Autonomous Variables: These variables have a weak drive power and weak dependence power. In this cluster we have six variables. Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Cross functional team building (E6), Organization Culture (E7) and Information System Infrastructure (E9).

Cluster 2 - Dependence Variables: These variables have a weak drive power but strong dependence power. In this cluster we have twelve variables. Green process and Technology (E8), Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11), Supplier Flexibility (E12), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19) and Procurement Excellence (E20).

Cluster 3 - Linkage Variables: These variables have a strong drive power as well as strong dependence power. Linkage variables are very sensitive and unstable. Any action on these variables will trigger an effect on other variables and also a feedback on themselves. In this cluster we have no variables.

Cluster 4 - Driving Variables: These variables have a strong drive power but weak dependence power. In this cluster we have two variables. Government policy and Regulations (E1) and Continuous education of employees (E5).

Defuzzified Reachability Matrix

The Defuzzified reachability matrix with fuzzy linguistic terms VH, H, as 1 and rest as 0 is shown in Table 4 (Appendix).

Defuzzified Reachability Matrix and Transitivity Check

The paired comparisons are translated in the form of reachability Matrix. The matrix has been also checked for transitivity rule. A final reachability matrix, post transitivity check is presented in Table 5 (Appendix).

Driving Power and Dependence Power Matrix (MICMAC) Based on Defuzzified Reachability Matrix from Table 5

See Figure 2.

Discussion on MICMAC Analysis Based on Defuzzified Reachability Matrix

Cluster 1 - Autonomous Variables: These variables have a weak drive power and weak dependence power. In this cluster we have no variables.

Cluster 2 - Dependent Variables: These variables have a weak drive power but strong dependence power. In this cluster we have nine variables. Information System Infrastructure (E9), Suppliers' capability to Innovate (E13), Supply risk management (E14), Trust building in suppliers (E15), Low supplier lead time (E16), Customer Satisfaction (E17), Annual Savings from green procurement practices (E18), Annual Saving of natural resources (E19), Procurement Excellence (E20).

Cluster 3 - Linkage Variables: These variables have a strong drive power as well as strong dependence power. Linkage variables are very sensitive and unstable. Any action on these variables will trigger an effect on other variables and also a feedback on themselves. In this cluster we have three variables. Green Design (E10), Re-use, Re-engineering and Recycling of products and materials (E11) and Supplier Flexibility (E12).

Cluster 4 - Driving Variables: These variables have a strong drive power but weak de-

Figure 2. MICMAC analysis based on Table 6

pendence power. In this cluster we have eight variables. Government policy and Regulations (E1), Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Continuous education of employees (E5), Cross functional team building (E6), Organization Culture (E7), and Green process and Technology (E8).

Level Partition on Reachability Matrix

The final reachability matrix obtained in Table 5 is now partitioned into different levels. After the first iteration, the driver classified to level 1 is discarded and the partitioning procedure is repeated on the remaining drivers to determine the level 2. These iterations are continued until the level of each driver has been determined and presented in Table 6 (Appendix).

TISM Diagram

The connective and interpretive information contained in the interpretive direct interaction

matrix and diagraph is used to derive the TISM. The nodes in the diagraph are replaced by the interpretation of elements placed in boxes. The interpretation of the cells of interpretive direct interaction matrix is depicted by the side of the respective links in the structural model. The final TISM model after removing the transitive links is presented in Figure 3.

CONCLUSION

In the current study author proposes Fuzzy TISM method for identifying the interrelationships among elements influencing green procurement. Due to incorporation of fuzziness in TISM the decision makers have the flexibility in assigning the level of influence of pair wise elements. Apart from wider flexibility Fuzzy TISM also enhance the quality of decision making. The findings from the TISM model show that Customer Satisfaction is in level 1, Annual Savings from green procurement practices, Annual Saving of natural resources and Procurement Excellence are in level 2, Supply risk management is in level 3, Information System Infrastructure and Low supplier lead time is

Figure 3. TISM diagraph

in level 4, Suppliers' capability to Innovate and Trust building in suppliers is in level 5, Supplier Flexibility is in level 6, Re-use, Re-engineering and Recycling of products and materials is in level 7, Green Design is in level 8, Green process and Technology is in level 9, Continuous education of employees, Cross functional team building and Organization Culture is in level 10, Total Quality Environmental management and Management Review is in level 11 and Government policy and Regulations and Management Support are in the bottom level.

The driving factors which emerged from Fuzzy TISM and MICMAC analyses are Government policy and Regulations (E1), Total Quality Environmental management (E2), Management Support (E3), Management Review (E4), Continuous education of employees (E5), Cross functional team building (E6), Organization Culture (E7), and Green process and Technology (E8). These elements are the key players which must be considered while planning green procurement programs.

LIMITATIONS AND DIRECTIONS OF FUTURE RESEARCH

The present research has certain limitations. The model is developed purely based on interview with five procurement management experts from the manufacturing sector. In future studies the author proposes to statistically validate the model using big sample size and further extend theory of green procurement.

KEY TERMS AND DEFINITIONS

Green Procurement: Green Procurement is procuring of products and services that cause minimal adverse environmental impacts. It incorporates human health, social and environmental concerns into the search for high quality products and services at competitive prices.

Total Interpretive Structural Modeling (TISM): Fuzzy TISM is an extension of Interpre-

tive structural modeling (ISM) technique. ISM methodology, transforms unclear, poorly articulated models of systems into clear, well-defined models. ISM uses experts to judge the variables, and the relations among the variables are interpreted. ISM depends on the experts' knowledge and familiarity with the firm, its operations, and its industry. ISM generates deep knowledge of the subject and is greatly helpful for practitioners.

Syed Rafay Hasan

Tennessee Technological University, USA

INTRODUCTION

With 19320 TW-hr/yr consumption of electrical energy in the entire world nowadays, the traditional unidirectional power transmission grids are struggling to survive as the number of fluctuations, blackouts and outages is tremendously growing since the last decade (Gao et al., 2012). More reliable and safe distribution networks have become a dire requirement due to the safety and financial-critical nature of electricity these days. For example, a blackout per minute across Silicon Valley costs 75 million and 1 million dollars for Sun Microsystems alone. There are numerous environmental concerns with the present-age power generation methods as well since these methods are largely dependent on fossil fuels, which result in global warming and carbon-dioxide emissions. For example, the United States power system alone is responsible for 40 percent of carbon emission nationwide (Hledik, 2009). Thus renewable energy resources, like solar and wind based solutions, are extensively being advocated throughout the world but the traditional grid does not facilitate their integration in the national grids. Moreover, the traditional power grids are not very efficient in terms of distribution loss management as well. For example, about 17 percent of electrical energy generated in the year 2011 by Pakistan was wasted in distribution systems. Similarly, the problem of electricity theft is also a growing concern in traditional grids.

Smart grids can overcome the above mentioned shortcomings by providing an alternative electric power transmission framework that comprises of Intelligence based Electronic Devices (IED) (Momoh, 2012) for detecting and correcting faults, and advanced metering infrastructure (AMI), to facilitate the integration of multiple renewable energy sources. Some of the distinguishing characteristics of smart grids compared to traditional power grids include:

- **Safety and Reliability:** Smart grids can predict unforeseen situations and autonomously react accordingly to prevent them (e.g., isolating the faulty component of the grid from the entire system (Farhangi, 2010)) and hence improve the safety and reliability (Moslehi and Kumar, 2010) of power distribution and save millions of dollars.
- **Cost-Effectiveness:** Smart grids provide real-time tariff information to the consumers so that they can manage their loads to save energy and costs (Li et al., 2010).
- **Efficiency:** Smart grids allow optional usage of the assets to maximize the efficiency of the grid and thus can have a major performance impact. For example, according to the US Department of Energy (DOE), just a 5% increase in grid efficiency can have the same impact as if fuel and greenhouse gas emissions are eliminated from 53 million cars.

DOI: 10.4018/978-1-5225-2255-3.ch271

- **Security:** Smart grids allow more secure electrical networks, by using tools like smart meters, and thus electricity theft can be minimized (Khurana et al., 2010, Metke and Ekl, 2010).
- **Environmental Friendliness:** Smart grid allows the integration of environmental friendly generation methods and is inline with the recent advancements in renewable energy research (RER) (Ipakchi and Albuyeh, 2009).

Based on above-mentioned capabilities, the National Academy of Engineering listed “electrification as made possible by the grid” as the most significant engineering achievement of the 20th Century.

Due to the inherent randomness of smart grids, including variable loads, peak consumption times and renewable energy sources with generation capacity depending on varying weather conditions, there is a lot of interest in rigorously analyzing the voltages and load profiles for resilient and effective power delivery to the users. Besides providing means for effectively managing the energy distribution, these profiles can be used by the consumers to change their loads by a smart device from anywhere as per their requirements. Load flow analysis (Van Benthem and Doets, 2001) fulfills the above-mentioned requirements and allows us to find the magnitude and phase angle of the voltage and the real and reactive power flowing in each bus of the smart grid and the optimal parameters for various components, like inductors, conductors, transformers, and shunt capacitors. It also provides statistics about the behavior of the system during on-peak and off-peak loads in order to identify and plan the contingencies. Moreover, load flow studies help us in conducting short-circuit fault analysis and in finding the stability and the steady-state operating state of an electric power system by calculating the voltage drop on each feeder, the power flow in all branches and feeder circuits, X/R ratio in line impedances and the voltage at each bus. Finally, load flow studies can determine if system volt-

ages remain within the given specifications and if any of the expensive equipment of the grid is overloaded. The results of load flow analysis are used to make key decisions and ensure a safe and reliable power distribution.

There are various uncertain and random elements associated with the load consumption in smart grids. For example, the usage of consumer appliances depends on weather conditions and the time of the day. The distributed generation and usage of storage cells also plays a key role in varying the electrical demand. Some of the key factors that influence the loads in smart grids and must be taken into consideration for load flow analysis of smart grids include weather conditions, time-of-day, arbitrary disturbances, electricity prices, demand response, storage cells and electric vehicles.

BACKGROUND

There are various uncertain and random elements associated with the load consumption in smart grids. For example, the usage of consumer appliances depends on weather conditions and the time of the day. The distributed generation and usage of storage cells also plays a key role in varying the electrical demand. The smart grid components may fail randomly and either self-repair or need manual repair to restore their operation. Some components may also have back-up protection. Similarly, the influence of electricity prices on the energy demand cannot be neglected as higher prices usually result in the reduction of energy consumption. Moreover, in smart grids, the consumers are more cautious about costs since they can get the real-time tariffs using smart meters. Time-of-Use (TOU) pricing scheme, which offers low off peak rates, encourages consumers to shift their loads to off peak hours. Moreover, electric vehicles (EVs) also greatly influence load profiles since their charging consumes a significant amount of energy and thus is recommended to be done in the off peak times.

The load flow analysis mainly involves studying the behavior of node voltages and the power entering and leaving the nodes in a smart grid while considering the above-mentioned elements of randomness and uncertainty. In this section, we describe some of the key techniques that have been used for load flow analysis.

Numerical Methods

Numerical methods are one of most widely used analysis methods for load flow. Primarily, these methods are used to solve the following nodal equation:

$$I = V \cdot Y_{bus} \quad (1)$$

where I is the N vector of current in each bus, V is the N vector bus voltages and Y_{bus} is the admittance bus matrix. Iterative numerical methods can solve the Equation (1), however, they generate approximate results mainly because the precision of the results is directly proportional to the number of iterations. Some of the frequently used numerical methods for load flow analysis are described in detail below:

Gauss-Seidel Method

The Gauss-Seidel method (Chapra Steven and Canale Raymond, 2008) is a widely used iterative approach for solving linear equations based on an initial guess. In load flow analysis, we develop an admittance matrix using the Kirchhoffs current law and then an iterative method is used to solve the scheduled reactive and real power at each bus, respectively. The final node voltage is determined in an iterative manner by using intermediate values of node voltages obtained after each iteration. This process converges linearly if the initial estimation is close to the unknown value. A variant of modified Gauss-Seidel method has been used for power flow calculations in (Teng, 2002). Gauss-Seidel method shows slower rates of convergence but its main strength is that it does not need to solve a

complex matrix system. Gauss-Seidel method is not suitable for radial distribution systems where there are branch connections between a large set of surrounding buses (Momoh, 2012).

Newton-Raphson Method

The Newton-Raphson (NR) method is another iterative method to solve non-linear load flow equations. The sensitivity matrix is determined from inverting the Jacobian matrix, which consists of the injected power equations. The NR method has been used to solve three phase power flow equations in (Le Nguyen, 1997). This method is very useful for large systems. But it is computationally inefficient because it does not take advantage of the radial distribution systems (Momoh, 2012). Moreover, the method also fails if the Jacobian matrix is singular. Finally, in the case of a low X/R ratio value, the NR method becomes ill conditioned (Momoh, 2012). On the other hand, it offers a fast convergence rate.

Fast Decouple Method

The Fast Decouple method is one of the most effective techniques used in power system analysis and design. Just like the Newton-Raphson method, it also utilizes the Jacobian matrix. On contrary, in this technique small angle approximation is used to calculate the relatively smaller elements of the Jacobian matrix. However, this method shows poor convergence for low values of the X/R ratio (Iwamoto and Tamura, 1981). This method has been successfully used for three phase power flow studies in (Zimmerman and Chiang, 1995).

Besides using the above mentioned mainstream numerical methods for load flow analysis, the other significant contributions in this direction include using the interval arithmetic (Wang and Alvarado, 1992), the holomorphic embedded load flow method (Trias, 2012) and an optimal multiplier method for ill conditioned systems (Iwamoto and Tamura, 1981). Other significant methods include Zero-mismatch method, Ward and Hale method,

Glimm and Stagg method and Secondary adjustment method for load flow analysis and more details about them are discussed in (Stott, 1974).

Simulation Methods

The main idea behind simulation is to construct a computer-based model of the given system and then analyze the desired load flow properties by observing the behavior of the model under different test cases. A number of dedicated simulations packages for analyzing power distribution systems are available and have been used to analyze the following key aspects (Glover et al., 2011):

- Arc flash hazard and fault analysis,
- Circuit breaker duty,
- Demand management,
- Distribution reliability evaluation,
- Power factor correction,
- Power loss computations,
- Components sizing,
- Voltages/VAR optimization,
- Power quality and reliability,
- Harmonic analysis, and
- Fault detection.

Simulation is a very user-friendly analysis approach since the analysis requires test pattern generation only. On the down side, simulation cannot guarantee absolute correctness of analysis because there is always a possibility that a corner case is missed in test patterns used for analysis. Some of the common load flow software are explained below:

Electrical Transient Analyzer Program

The Electrical Transient Analyzer Program (ETAP) simulator, developed by Operation Technology Inc., is one of the most widely used load flow analysis software. It allows the user to utilize the built-in templates to quickly construct a model of the entire electrical network. The ETAP simulator can be used

to analyze integrated power systems (Khan et al., 2009) and has an ability to track up to 10 million load items. In (Sedighizadeh and Rezazadeh, 2008), a genetic algorithm is used for optimal allocation of distributed generation for improved voltage profile and the correctness of results is evaluated by ETAP. The power flow analysis package in ETAP provides both Newton-Raphson and Accelerated Gauss-Seidel method to solve power flow equations. ETAP offers two methods to calculate the X/R ratio. The first method finds the equivalent resistance and reactance of the entire system, to get a single value X/R ratio for a given location. In the second method, individual branch current contributions (each with a separate X/R ratio) are combined into a single X/R ratio. ETAP has also been used to analyze different distribution system models to minimize their power losses (Ramesh et al., 2009). The developers of ETAP claim that ETAP can also serve as a complete smart grid analysis tool.

GridLAB-D

GridLAB-D is a recently developed open-source power system modeling and simulation tool by the Pacific Northwest National Laboratory (PNNL) of the US DOE. It offers distributed energy resource modeling, integration of transmission and distribution systems, SCADA and metering models. An interesting feature is its external links to MySQL, MATLAB, MS-EXCEL and MS-ACCESS (Schneider et al., 2009). This tool offers timing models ranging from a few seconds to decades. GridLAB-D gives a simulation environment that can be incorporated with a variety of data management and analysis tools. It divides the power flow problem in two parts, i.e., 1) transmission and 2) distribution. It uses Gauss-Seidel iterative method to solve power flows at the transmission side while Forward and Backward Sweep (FBS) method to solve power flow problems at the distribution side (Schneider et al., 2009). Instead of the FBS method, the newer versions of GridLAB-D utilize the Gauss Seidel Three Phase Current Injection

method due to the inability of FBS to handle networked distributions (Schneider et al., 2009).

Use of Matlab for Load Flow Simulations

Although MATLAB, which is a high level language for doing intense numerical computations and programming, is not developed particularly for load flow analysis but it can be used for that purpose. Given the general-purpose nature of MATLAB, it provides a very flexible environment for load flow analysis. For example, the NR method is programmed to solve a 5-bus system on MATLAB (Mallick and Hota, 2015). The Power System Analysis Toolbox (PSAT), which is an open source MATLAB toolbox, has been used for power flow calculations (Milano, 2005).

Power World Simulator

The Power World simulator is a commercial grade power system analysis and simulation package developed by the Power World Corporation. It is designed to simulate high voltage power system operations on a time frame ranging from several minutes to several days. The software can solve up to 100,000 buses with high efficiency. It extensively uses state-of-the-art graphics for better and easy understanding. The simulator is mainly based on the Newton-Raphson method for iteratively solving non-linear equations for power flows. Load flow analysis by fast decouple method is also an option available in this simulator. It uses three nested loops to solve power flows.

Simulation and testing are the state-of-the-art analysis techniques; however, as we have seen that they also use the numerical methods for their computations and thus cannot guarantee accuracy. Moreover, the main idea behind simulation and testing methods is to approximate a solution to a query by observing a subset of each probable run. Hence, it is possible that a system bug may not be detected during the simulation-based analysis. Moreover, system models, used in simulation

cannot capture the true random behaviors, such as frequent changes in renewable energy generation, variations in network configurations and the peak loads, which are very frequently encountered in smart grids. In most cases, simulation based methods rely on pseudo random number generation methods for modeling these elements of randomness and the reliability of the analysis is dependent on the quality of these random number generators.

Computational Intelligence

Computational Intelligence (CI) methods provide a very efficient alternative for verifying and analyzing complex systems that exhibit random behavior. Thus, the grid can be controlled more reliably and more rapidly than humans by multi-variable nonlinear optimal controller based on CI, without requiring a mathematical model of the grid.

CI techniques primarily consist of Artificial Neural Networks (ANNs) (Haykin, 1994), evolutionary computation (Back et al., 1997), non-linear programming (Sasson, 1969) and fuzzy logic systems (Takagi and Sugeno, 1985). ANN based load forecaster is one of the most successful applications of CI for predicting load flows in an uncertain environment. Evolutionary computational techniques tend to solve combinatorial optimization techniques by learning and adapting to new situations and are primarily based on Genetic Algorithm (GA), particle swarm optimization (PSO) and ant colony optimization methods (Vlachogiannis et al., 2005). GAs have been used to analyze the Reactive power (VAR) with real-time operation that contains randomness and uncertainty (Bakirtzis et al., 2002). PSO (del Valle et al., 2008) uses simple mechanism that mimics social behavior of bird flocking and fish schooling to guide the particles search for globally optimal solution. In (Miranda and Saraiva, 1991), fuzzy modeling is used for optimal load flow. Fuzzy logic is also used for developing a unified power flow controller for damping the power system oscillations (Eldamaty et al., 2005). Linear, nonlinear, dynamic and integer program-

ming methods have also been used for load flow analysis (Momoh, 2012). The above-mentioned CI based techniques have also been used to analyze various power systems (Saxena et al., 2010) including maintenance scheduling, long-term system expansion and planning and load forecasting. A very comprehensive overview about CI techniques and the advantages and disadvantages of Genetic Algorithm (GA), Simulated Annealing (SA), Artificial Neural Networks (ANNs), Expert Systems (ES) and few other techniques for analyzing power distribution systems is presented in (Saxena et al., 2010).

CI techniques of linear programming, non-linear programming, quadratic programming and Newton based techniques (Sun et al., 1984) have also been successfully used to solve various Optimal Power Flow (OPF) problems (Habibollahzadeh et al., 1989, Aoki et al., 1987). These techniques have certain drawbacks as mentioned in (Abido, 2002), like, non-linear programming has convergence problems and it is complex, quadratic programming techniques have problems with cost approximation. Newton based techniques may have convergence failure due to inappropriate initial conditions, hence, they are sensitive to initial conditions. In (Abido, 2002), a particle swarm optimization technique is proposed to do OPF.

Probabilistic Load Flow

Given the large number of uncertainties involved in the load flow analysis of smart grids, probabilistic analysis methods have also been used in this domain. Probabilistic Load Flow (PLF) is primarily done by using Monte Carlo (MC) simulations and the convolution method through Fast Fourier Transforms (FFT). These MC simulations are very time consuming since a large number of samples are usually used. An extended form of PLF that supports non-linear load flow equations is presented in (Allan et al., 1976) based on numerical methods. Another technique, known as Stochastic Load Flow (SLF) (Vorsic et al., 1991), is based on the assumption that the states of the system

and power flow outputs are normally distributed. SLF deals with short time uncertainties and is only effective for analyzing system operation and thus the reliability of this method has been questioned (Anders, 1989). PLF has been used in (Allan et al., 1974) for analyzing power flows where the nodal loads and generation are defined as random variables and power flow is computed as a probability density function.

Multi-linear simulation algorithm has demonstrated better results than the MC simulation based methods (Da Silva and Arienti, 1990). Similarly, the method of combined cumulants and Gram-Charlier expansion for probabilistic load flow computation (Zhang and Lee, 2004) has reported a significantly improved performance. With this method, the probability density function of the transmission line flows is obtained. It determines the effect of prolonged uncertainty of transmission network. It also provides a new way of calculating probability density function which requires reduced storage, is applicable to larger systems and is faster than Monte Carlo simulations. It is useful in system expansion planning. Moreover, it also ensures better approximation of the cumulative distribution function curve. This method was practically demonstrated on a WSCC (Western Systems Coordinating Council) test system, which consists of 179 buses and 263 lines. The probability of any overloaded line can be easily computed through this method. The probabilistic load flow analysis using an algorithm based on the point estimate method is given in (Su, 2005). It is based on an assumption that the uncertainties of line parameters and injections in the bus can be measured. The method allows any deterministic load-flow program to be used. In order to calculate the statistical moments of load flow solution distribution for a system having m uncertain parameters, $2m$ calculations of load flow are used and the value of the solution is weighted at $2m$ locations. These moments are then used in probability density fittings. This method has been tested on several IEEE test systems and it is verified that performance of point estimate method

is better than Monte Carlo simulation and it also requires less number of computations. A detailed comparison between the cumulants method and the point estimate method is presented in (Li and Zhang, 2009) with respect to the load flow analysis.

Analyzing random branch outages in load flow is another area where probabilistic load flow is considerably used since conventional load flow methods cannot cater such problems (Hu and Wang, 2006). PLF allows us to solve discrete distribution part of each state and output variable. The effect of branch outage is greater on system state than uncertainties caused by nodal power injections. For simplifying the convolution of random variables, moments and cumulants are used. Branch outages are simulated by injecting the virtual power to the related nodes. The resulting distribution is found by convolving continuous and discrete distributions. The Dynamic Stochastic Optimal Power Flow (DSOPF) (Momoh, 2009), which is based on Adaptive Dynamic Programming (ADP) technique, is another stochastic method for PLF. ADP tends to cope with the complex power system problems, which can be predicted under uncertainty conditions, and it is useful where there is not enough prior knowledge. These tools usually ensure robustness, scalability, stochasticity, predictivity, adaptability and acquisition of instantaneous data.

FUTURE RESEARCH DIRECTIONS

All the above-mentioned techniques are found to be quite scalable and user-friendly but cannot guarantee the accuracy of the analysis results. The main reasons behind the inaccuracies in the result include the usage of computer-arithmetic based models, which contain round-off errors, and the sampling based nature of the analysis, i.e., the models are analyzed for a subset of all possible scenarios due to limited computational resources. Given the safety-critical nature of smart-grids, the accuracy of load flow analysis results is the most desirable feature, since an undetected fault

in the smart grid system can have major impact. For example, the analysis inaccuracy limitations have been reported as the main causes behind the 2003 Northeast blackout in the United States and Canada (Poulsen, 2004a),(Poulsen, 2004b) which approximately affected 55 Million people. As a complementary approach, formal methods (Abrial, 2009) which are computer based mathematical analysis tools, can be used to overcome the inaccuracy limitations in the domain of load flow analysis. However, to the best of our knowledge, no prior work regarding the formal load flow analysis exists so far. In order to fill this gap, we recommend to use probabilistic model checking (J. Rutten and Parker, 2004), which is a widely used formal method for analyzing Markovian models, to ensure accurate results of load flow analysis of smart grids.

CONCLUSION

Load flow analysis plays a vital role in safe and effective working of the smart grid system and a number of analysis methods have been used in this domain. This paper presents a brief overview about smart grids and the main factors affecting the loads in smart grids. This information can be utilized to understand the random and uncertain components in smart grids and thus model them appropriately in their load flow analysis, which can be conducted using Numerical methods, Simulation methods, Computational intelligence and probabilistic load flow methods. Each of these analysis methods have their own advantages and disadvantages and they have been highlighted in this chapter.

KEY TERMS AND DEFINITIONS

Asset Management Systems: Asset management of smart grids is a core requirement due to the huge investments involved. For example, according to the US Department Of Energy (DOE), around 1.5 trillion dollars have been invested in the US electricity infrastructure so far. Asset management applies to both tangible and intangible assets.

Distribution Management System: The Distribution Management System (DMS) may be regarded as the control center of the smart grid. The DMS mainly uses the fault location, Geographic Information Systems (GIS) and Outage Management System (OMS) to improve the reliability of the smart grid by reducing outages and sustaining the frequency and voltage levels. The most important role of DMS is to check the faults and isolate the faulty part out of the system. The “intelligent nodes” of the DMS can communicate with one-another periodically and if a fault occurs then they work together to reconfigure the system.

Energy Management System: The Energy Management System (EMS) is used for monitoring and controlling the performance of the generation and transmission system. It allows getting real-time updates from power plants about their conditions and generation parameters. The monitor and control functions are implemented through Supervisory Control and Data Acquisition (SCADA).

Renewable Energy Integration: Integrating various renewable energy sources is the most desirable feature of smart grids. However, this component faces various challenges. Advanced energy storage at the transmission, distribution, and residential levels, Static VAR compensators and synchro-phasors within the transmission grid, dynamic pricing demand response, micro grids, virtual power plants, and smart wind and solar technologies are some of the tools for Renewable Energy Integration (REI).

E

Methodology of Climate Change Impact Assessment on Forests

Mostafa Jafari

Regional Institute of Forest and Rangelands (RIFR), Iran

INTRODUCTION

Climate change is one of the main challenging issues in various countries (Jafari, 2013b) in current century. Climate change and climate variability and Global Warming and its' effects on natural resources, plants, animal and in general on human life are among subjects that received attention of scientists and politicians in recent years. Climate change challenges need to be considered in various dimensions (Jafari, 2013c). To both understand the present climate and to predict future climate change, it is necessary to have both theory and empirical observation. Any study of climate change involves the construction (or reconstruction) of time series of climate data. How these climate data vary across time provides a measure (either quantitative or qualitative) of climate change. Types of climate data include temperature, precipitation (rainfall), wind, humidity, evapotranspiration, pressure and solar irradiance (aric, 2008). Climate change assessments and evaluation should be done by using recorded observation data as well as prepared and provided proxy data (Jafari, 2010). Plant ecophysiological study has very important role to recognize climate changes (Jafari, 2007). Trees and also woods can be used as archive of past events. Climate change will strongly affect water resources, plant communities and wildlife in the arid and semi-arid regions (FAO, 2009). Water, environment humidity and temperature are main factors of plant growth. Majority of plant and forest ecosystems on the earth are formed under these two main factors. Whatever amount of humidity and required water are available and also favorable temperature for plant growth cause

plant community reach higher plants and trees and forest ecosystems would develop. In fact plants are important climate indicators. Trees are not an exception. Plants, especially, trees are sensitive to their environmental changes, and tree-ring width is one of the reliable proxies of ambient environmental conditions. Climate and environmental changes affect natural ecosystems as well as planted forests (Kiaee and Jafari, 2014). Investigation of quantity and quality of these growths could help to consider past climatic conditions. Measuring and recording tree rings' widths and its' densities of early woods and late woods can provide valuable data resources to produce time series and consider its correlation with climate factors in the same time periods (Figure 1).

Seasonal changes in temperate climatic region effect on tree rings widths periodically. In spring and summer time plants grow better than unpleasant seasons like fall and winter. The outermost layer of a tree is composed of bark. Bark itself is composed of two tissues: an innermost layer of live phloem, and an outer layer of periderm (the bark 'proper'), which has an outermost layer of waterproofing cork (phellum) which protects the wood to some degree from insects, etc (Figure 2). The cork has its own cambium (phellogen) between the phloem and cork layer. Only the outermost layer of a tree is alive (essentially only the phellogen, phloem, cambium, and maturing xylem of the current year's growth). Consequently, the majority of the trunk does not require gaseous exchange. The bark is punctuated by lenticels, a sort of giant stoma, which allows the thin outermost living layers of the trunk to 'breathe' (Anonymous, 2008a),

Figure 1. Tree ring width and densities, *Fagus orientalis* (beech tree), Mazandaran province mid-elevation forest (MA II F3)
(Author, 2010)

Growths of the vascular cambium tissue produce wood as secondary xylem production. Sapwood is xylem that conveys water and dissolved minerals from the roots to the rest of the tree. The darker heartwood is older xylem that has been infiltrated by gums and resins and has lost

its ability to conduct water. Each growth layer is distinguished by early wood (springwood), composed of large thin-walled cells produced during the spring when water is usually abundant, and the denser latewood (summerwood), and composed of small cells with thick walls. Growth rings vary in

Figure 2. Anatomy of a tree trunk
(Encyclopedia Britannica, 2000)

width as a result of differing climatic conditions; in temperate climates, a ring is equivalent to one year's growth. Certain conducting cells form rays that carry water and dissolved substances radially across the xylem. Bark comprises the tissues outside the vascular cambium, including secondary phloem (which transports food made in the leaves to the rest of the tree), cork-producing cells (cork cambium), and cork cells. The outer bark, composed of dead tissue, protects the inner region from injury, disease, and desiccation (Encyclopedia Britannica, 2006). A big trunk of a harvested tree can be use as an archive of data and may provide its life long time series (Figure 3)(Jafari, 2010).

Main objectives of dendrochronology are: a) Put the present in perspective of the past, b) Better understand current environmental processes and conditions, and c) Improve understanding of possible environmental issues of the future. To meet these objectives, the exact year of formation of each growth ring must be known: a) Merely counting rings doesn't ensure accurate dating, and b) Crossdating, also known as pattern matching, ensures accurate dating (Sheppard, 2013).

BACKGROUND

Dendrochronology is an accepted and reliable method in considering climate change impact on forest ecosystem through study tree ring widths (Jafari, 2015). The cambium of the trees growing in temperate zones becomes dormant in the falls and reactivates each spring. This leads to annual rings and the vessels produced in the spring are often larger than in the fall; the large vessels allow for rapid sap movement in the spring, whereas the narrow vessels minimize the risk of cavitations under dry conditions in late summer. This leads to a ring-porous pattern in the wood as opposed to the diffuse porous pattern where vessels are more even in size. As trees age the vessels in the center of the stem become air-filled and cease to carry water; they still function for support and storage of waste products, some of which are colored; this is the heartwood in contrast to the sapwood which carries water and is confined to the outer few annual rings (The Ohio State University, 2013).

Recording temperature and using thermometers have only been widely used since around 1850. Thus, the instrumental record for earlier

*Figure 3. Hyrcanian forest research site, an old trunk of Fagus orientalis L. (Asalem, Guilan province forest)
(Jafari, 2010)*

times is quite poor and full of gaps. Essentially nothing is available in the way of quantitative measurements of weather conditions for the time before 1800 A.D. To reconstruct climate change, therefore, we need to use indirect indicators. One source of information is historical records: logs, dairies, lists on when the wine harvest began, reports on when the ice first broke up in a northern river, or when the cherry trees first blossomed. In some cases, such reports go back hundreds of years, although rarely in unbroken sequence. Logs and dairies are treasured finds; they do not exist for most regions of the planet (Anonymous, 2008b).

Climate factors data can be measured by direct observation in different meteorological station (like climatology and synoptic stations) or can be recorded by different instrument in different locations and with different time intervals. This information is more or less confidential for judgments on the past events, and good tools for the future projections.

Applications of Dendrochronology

As definition point of view, the word dendrochronology is composed of: dendro (using trees, or more specifically the growth rings of trees), chrono (time, or more specifically events in past time), and logy (the study of). Applications in dendrochronology include: ecology (insect outbreaks, forest stand structure, past fires) (Jafari, 2012a),

climatology (past droughts or cold periods), geology (past earthquakes, volcanic eruptions), and anthropology (past construction, habitation, and abandonment of societies) (Sheppard, 2013). Also some new terms provided (Jafari, 2013a) for related applications such as, dendro-productivity (Jafari & Khoranke, 2013), dendro-genetic (Jafari *et al.*, 2012b), dendro-medical (Jafari, 2014a).

In region where the seasons provide clear seasonal climate difference, trees develop annual rings of different properties depending on weather, rain, temperature, soil pH, plant nutrition, CO₂ concentration, etc. in different years. These variations are used in dendroclimatology to infer past climate variations. Annual rings width of old trees wood sample is valuable data source as a live archive document for past climate changes, if year of growth and cross dating be well recognized. In case of sample from standing live trees, growth year is identifiable. But in case of wood samples, which could be found in archeological sites, recognizing growth year by producing skeleton graph and cross dating is necessary. Wood samples could show the years of past events like fire, drought or flood in growing site of sample tree. Fire-scarred ponderosa pine (*Pinus ponderosa*) from Ashenfelter Basin, Laramie Peak, Wyoming, (Figure 4). Low to moderate intensity fires that burned through a forest may injure or scar surviving trees, leaving a clear record of their passage. (Swetnam and Baisan, 2002)

Proxy Data and Climate Change

Climatologists who study past—or paleo—climates (Paleo-climatologists) use the term “proxy” to describe a way that climate change is recorded in nature, within geological materials such as ocean or lake sediments, tree-rings, coral growth-bands, ice-cores, and cave deposits.

For a proxy to be useful, it must first be established that the proxy (i.e. tree-ring width, stable isotope composition of ice, sediment composition) is in fact sensitive to changes in temperature (or some other environmental parameter). This phase of research is known as calibration of the proxy. Perhaps the most frequently used temperature proxy is the relative abundance of microfossils in sediments. That microfossils bear witness to temperature was recognized early in the history of oceanography.

Measuring and recording of tree-ring width is another reliable source of proxy of ambient environmental conditions. When a tree grows at high elevation, near the tree limit, its growth is limited by temperature, and the thickness of its growth rings contains clues about whether the growing season was warm or cold. An equation can then be written relating the changes in ring width to temperature change. Similarly, if the growth is limited by water (say, in a warm semi-arid setting) the ring width can be used to calculate changes in rainfall. Climate proxies have been utilized to provide a semi-quantitative record of average temperature in the Northern Hemisphere back to 1000 A.D (Anonymous, 2008b).

To provide paleo proxy data paleo-climatologists gather proxy data from natural recorders of climate variability such as tree rings, ice cores, fossil pollen, ocean sediments, corals and historical data. By analyzing records taken from these and other proxy sources, scientists can extend our understanding of climate far beyond the 100+ year instrumental record.

Principle sources of the major types of proxy climatic data for palaeoclimatic reconstructions can be categorized as following groups (Jafari,

2010): Glaciological (Ice Cores), Oxygen isotopes, Physical properties, Trace element & micro-particle concentrations

- **Geological:** A. Sediments, 1. Marine (ocean sediment cores), i) Organic sediments (plank-tonic & benthic fossils), Oxygen isotopes, Faunal & floral abundances, Morphological variations, ii) Inorganic sediments: Mineralogical composition & surface texture, Distribution of terrigenous material (provided by river erosion), Ice-rafted debris.
- **Geochemistry:** 2. Terrestrial, Periglacial features, Glacial deposits & erosion features, Glacio-eustatic features (shorelines and sea level changes), Aeolian deposits (sand dunes), Lacustrine deposits/varves (related to the lakes), B. Sedimentary Rocks, Facies analysis, Fossil/microfossil analysis, Mineral analysis Isotope geochemistry.
- **Biological:** Tree rings (width, density, isotope analysis), Pollen (species, abundances), Insects.
- **Historical:** Meteorological records, Parameteorological records (environmental indicators), Phenological records (biological indicators).

Proxy material differs according to its: a) its spatial coverage; b) the period to which it pertains; and c) its ability to resolve events accurately in time (Bradley, 1985). Some proxy records, for example ocean floor sediments, reveal information about long periods of climatic change and evolution, with a low-frequency resolution. Others, such as tree rings are useful only during the last 10,000 years at most, but offer a high frequency (annual) resolution. The choice of proxy record (as with the choice of instrumental record) very much depends on what physical mechanism is under review. As noted, climate responds to different forcing mechanisms over different time scales, and proxy materials will contain necessary cli-

matic information on these to a greater or lesser extent, depending on the three factors mentioned (aric, 2008).

Natural Archives

Growth conditions can be recorded in tree rings. A wide ring could be define as plenty of warm days and sufficient water, a narrow ring means nasty conditions, either a short growing seasons because summer was late in coming (up on the mountain), or a severe water shortage (in the foothills, in areas where water is limiting). The mixture of conditions recorded (time of snow-melt, intensity of winter rain, temperature in June, etc.) depends on what a given tree cares about in terms of growth. Hence, a tree is a “reporter,” and the same is true for all other organisms recording climate change. What a scientist can extract from tree rings depends on how many properties of a ring can be measured (width, density of early wood, density and width of wood grown late in the season), how clever the statistical methods are, and how well the items of interest (say, spring temperature or annual rainfall) are correlated with the properties measured. For instance, special measurements can be made on the isotope chemistry of the wood. This kind of information can yield insights on the composition of the rainfall (from oxygen isotopes) and on the rate of photosynthesis (from carbon isotopes) (Anonymous, 2008b).

While tree growth is influenced by climatic conditions, patterns in tree-ring widths, density, and isotopic composition reflect variations in climate. In temperate regions where there is a distinct growing season, trees generally produce one ring a year, and thus record the climatic conditions of each year. Trees can grow to be hundreds to thousands of years old and can contain annually-resolved records of climate for centuries to millennia.

Tree Rings Measurement Instruments

E

Outcome from dendrochronological research studies played an important role in the early days of radiocarbon dating. Tree rings provided truly known-age material needed to check the accuracy of the carbon 14 dating method. During the late 1950s, several scientists (notably the Dutchman Hessel de Vries) were able to confirm the discrepancy between radiocarbon ages and calendar ages through results gathered from carbon dating rings of trees. The tree rings were dated through dendrochronology.

Even now, tree rings are still used to calibrate radiocarbon determinations. Libraries of tree rings of different calendar ages are now available to provide records extending back over the last 11,000 years. The trees often used as references are the bristlecone pine (*Pinus aristata*) found in the USA and waterlogged Oak (*Quercus* sp.) in Ireland and Germany. Radiocarbon dating laboratories have been known to use data from other species of trees (BETA, 2013).

Borer core samples submitted to the laboratory are registered, followed by preparation of optimal surfaces for analysis across several growth radii of the tree. Subsequently, tree-ring series are measured manually (Figure 5) and registered and or using specially designed measuring devices (Lintab and Aniol) connected to computers (Figure 6), screens and printers. The soft wares used for data storage, cross-correlation and statistical analyses are CATRAS and ITRDBLIB. Samples subject to wood anatomical determination are analyzed with light microscopy and compared against the laboratory’s extensive reference collection of European woody plants (Hammarlund, 2013). Major Equipment in the Biogeography/ Dendrochronology Laboratory currently houses one Velmex Measuring Machine connected to a

Stereozoom Microscope on a boom stand and a microcomputer analysis system. The lab equipment also includes: - incremento borers, - stereozoom microscopes, - belt sanders (4X24"), - desktop and laptop computers, - GPS units, Stihl Chain saw Stihl 046 with a 24" bar, Hand saws, - Hood, - cruiser packs, - Soil Sampling probes, - Munsell Charts, - Measuring tapes, - map tubes, - Paper straws, Poplar core mounts, skeleton plot paper (Indiana State University, 2013).

Discs or Borer Core Samples

The stem cross section is the best way to have a good surface on which to observe tree ring series. These discs can be sometimes obtain in co-operation with foresters when timbering is programmed. In most of the cases, cross dating and then measurements of ring-width as well as densitometry analysis are performed with small cores 4mm in diameter extracted from the tree by an increment borer. In order to avoid dissymmetry in radial tree-growth measurement 2 or 3

cores are extracted on each tree. Consequently, on each sampling site 20 to 45 cores are collected and brought back to the laboratory. Precise cares have to be taken in coring, particularly when densitometry analysis will be performed. The most important is the position of the borer on the trunk. In order to obtain lately an observation surface the most perfectly perpendicular to the long axis of tracheids and fibers, the borer has to be also positioned perpendicularly to trunk axis (TGTC, 2008).

In case which disc of harvested trunk is not available (Figure 7) or it is not possible to take disc, core sampling is an alternative. There are different types of drill instrument for this purpose (Figure 8). Increment borers are instruments that take a small cylindrical core from trees and allow determination if radial growth or age of the tree (Figure 8c). The borer consists of three parts (Figure 8): the case or handle, the borer bit, and the extractor. Increment borers come in various sizes, from 4 inches (101.6 mm) to 30 inches (762 mm) length or more. The ones which are in usual

use are in the 8-18 inch range (457.2 -203.2 mm). Smaller borers are used for small trees or where only recent growth is needed from larger trees (Figure 8a, b, and c, Figure 9).

In the field sampling experiment, when the cores remove from the borer, for the safety, it is needed to lay them into an increment core holder that has been pre-glued. Tightly wind the glued cores with cotton string (Figure 10) so as to apply pressure during the drying process (McCarthy, 2008).

Immediate observation of rings on cores extracted from the borer is rarely possible, and moreover rings width measurement quite impossible. Good observation and measurement need a perfect transverse section. After a correct reorientation of the core as the piece of wood was in the trunk, such a section is obtained either by refreshing with a razor blade or polishing the surface selected in order to obtain a plane surface allowing to access to the cell structure (TGTC, 2008).

Measured Data Analysis

A great number of laboratories in different part of the world have been established to study on wood and climate changes. Palaeo-climate changes are on the target of the most of these institutes. The International Tree-Ring Data Bank is maintained by the NOAA Paleoclimatology Program and World Data Center for Paleoclimatology. The Data Bank includes raw ring width or wood density measurements, and site chronologies (growth indices for a site). Tree-ring measurement series from other parameters are welcome as well. Reconstructed climate parameters, including North American Drought, are also available for some areas. Over 2000 sites on six continents are included (WDC, 2008). The objective of the measuring ring widths would be to develop tree-ring records of climate over the past several centuries, to understand inter-annual to century scale variability in climate. This study will improve the capability of understanding environmental variability and key features of the

regional environment, e.g. persistence of drought, reliability of stream flow (Hughes & Touchan, 1997). Analyzing data by using software by accuracy of 0.01 mm (Robinson & Evans 1980) or more accurate up to 0.001 mm.

Statistical Analysis of the Climate Factors

Tree-rings can provide continuous yearly paleoclimatic records for regions or periods of time with no instrumental climate data. However, different species respond to different climate parameters with, for example, some sensitive to moisture and others to temperature. For example four common species which grow in Northern Ireland and their suitability for climate reconstruction are beech, oak, ash and Scots pine. Beech and ash are the most sensitive to climate, with tree-ring widths more strongly influenced by precipitation and soil moisture in early summer than by temperature or sunshine. Oak is also sensitive to summer rainfall, whereas Scots pine is sensitive to maximum temperature and the soil temperature. The moisture-related parameters, rainfall and the Palmer Drought Severity Index (PDSI), and to a lesser extent, maximum and mean temperatures, can be reconstructed. Reconstructions of climate parameters with tree-rings as proxies may be relatively stable for some seasons such as May–July. The combinations of species are more successful in reconstructing climate than single species (García-Suárez *et al.*, 2009). The development of dendrochronological time series in order to analyze climate-growth relationships usually involves first a rigorous selection of trees and then the computation of the mean tree-growth measurement series. A change in the perspective, passing from an analysis of climate-growth relationships that typically focuses on the mean response of a species to investigating the whole range of individual responses among sample trees (Carrer, 2011).

Crossdating

Primary phase of crossdating work, under a good dissecting microscope, begins by counting backwards from the first known year behind the bark. Using a fine mechanical pencil, place a single dot on each decadal ring (e.g., 2010, 2000, 1990, etc.), place two dots on each 50-year ring (2010, 1960, 1910, etc.), and three dots on each century ring (2010, 1910, 1810, etc.). At this stage, these marks are just temporary year assignments. The actual years will be confirmed after skeleton plotting (McCarthy, 2008).
